Dr. Senn's book contains three papers: the first was read before the Congress of American Physicians and Surgeons, in Washington; the second was published in the Annals of Surgery; the third was read at the last meeting of the American Medical Association. They are all marked by the thoroughness which characterizes Dr. Senn's literary work, and deserve to be collected as a monument to his labors in connection with intestinal surgery.

It would be impossible, in the space we can spare, to give any adequate idea of the contents of this book; and this is not necessary, for Dr. Senn's work in intestinal surgery is now very well known, and the statement that we have here the results of his wide study, ingenious experimentation, and skiful practice, will indicate how valuable a contribution he makes to the literature of the subject.

We congratulate him upon the results he has achieved in this important field of surgery, and commend his book very heartily to the attention of the readers of the Reporter.

THE THEORY AND PRACTICE OF OBSTETRICS. By P. Cazeaux, Adjunct Professor in the Faculty of Medicine, Paris, etc. Remodeled and Rearranged by S. Tarnier, Prof. of Obstetrics and Diseases of Women and Children in the Faculty of Medicine, Paris. Eighth American Edition. Edited and Revised by Robt. J. Hess, M.D., Physician to The Northern Dispensary, Phila. With an Appendix by Paul F. Mundé, M.D., Prof. of Gynecology at the N. Y. Polyclinic, etc. Illustrated with Chromo-Lithographs, Lithographs, etc., and 175 wood engravings. 8vo, pp. xxxii, 1221. Philadelphia: P. Blakiston, Son & Co., 1889. Price $5.00.

It is unnecessary to speak of those features of this book which have made it popular for so many years—they are well known to all. Cazeaux and Tarnier's obstetrics will always possess much historical value, not only because it contains the elaborated views of the authors upon the principles and practice of obstetrics, but also because it contains a very full *résumé* of contemporary and older obstetric literature.

But is the present edition brought up to date by its revision and by its appendix? Unquestionably not. To mention only a few of the many sections which need revision or entire recasting, we would note the sections on embryotomy, Cæsarean section, symphyseotomy, induction of premature labor, the forceps, version, ergot, artificial delivery of the placenta, hemorrhage, ante-partum and post-partum, extra-uterine pregnancy, and placenta prævia—in fact about every subject of practical obstetrics. No mention is made of the improved Cæsarean section, its development, technique or results. We have simply a cut of Tarnier's forceps, but no account of the investigations which led to its invention or the principles upon which it works. Under "version" no mention whatever is made of combined internal and external version, as taught by Braxton Hicks and others—oftentimes an invaluable procedure, especially in the treatment of placenta prævia. No con-

sideration is given to the modern methods of treating placenta prævia—the methods of Barnes, Hicks, and Murphy, which have effected such a great saving of life. Did our space permit, this list of omissions and failures in revision could be very much enlarged To a certain extent the appendix by Mundé corrects or supplements the text, but unfortunately the topics discussed in the appendix cover but a small part of the field of obstetrics.

There is no sign by which the additions and alterations of the Editor can be distinguished. This does not seem fair to the Editor, to Cazeaux and Tarnier, nor to the reader. Had the usual custom been followed, the Editor's notes would have added to the value of the book as a working guide, without detracting from its historical value.

The illustrations are, with a few exceptions, unusually poor. The printing is apparently done from old plates.

We have told the exact truth about this book, and we are very much surprised to find the unqualified endorsement of a number of our most celebrated obstetricians printed on one of its fly leaves.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

231. Two Cases of Gunshot Wound of the Abdomen, Illustrating the Use of Rectal Insufflation with Hydrogen Gas as a Diagnostic Measure. By N. Senn, M.D., Milwaukee, Wis. From the *Medical News*, November 10, 1888. 9 pages.

232. Diseases of the Nose and Pharynx, and their Treatment. By W. Cheatham, M D, Louisville, Ky. From the *Virginia Medical Monthly*, December, 1888. 8 pages.

233. Report of Surgical Operations. By J. B. Luckie, M.D., Birmingham, Ala. 8 pages.

234. A Case of Tumor of the Cervical Region of the Spine. Operation and Death. By James Hendrie Lloyd, M.D., and John B. Deaver, M.D., Philadelphia. From the *Amer. Journal of the Med. Sciences*, December, 1888. 7 pages.

235. Acute Unilateral Optic Neuritis, with the Report of a Case. By G. E. De Schweinitz, M.D., Philadelphia. From the *Transactions of the Philadelphia County Med. Society*, October 10, 1888 7 pages.

236. Retrojection in Gonorrhœa. By E. R. Palmer, M.D., Louisville, Ky. From the *New York Medical Journal*, December 1, 1888. 7 pages

237. Medico-Legal Aspects of Some Injuries of the Spinal Cord. By James Burry, M.D., and F. W. Andrews, M.D., Chicago.

Remarks on Medico Legal Aspects of Some Injuries of the Spinal Cord. By Henry M. Lyman, M.D, Chicago. With Discussion. From the *Journal of the Amer. Med Association*, Dec. 15, 1888. 24 pages.

231. We have here an account of two cases in which he applied his now well known method for the detection of perforations of the intestine. Both of the cases demonstrated the great value of Senn's method and one of them the disadvantage of allowing much time to elapse before operating when the intestine has been perforated. In this case Dr. Senn first saw the patient twelve hours after he had been shot.

232. Dr. Cheatham advocates surgical interference for the relief of the effects of hypertrophied nasal tissue and bony ridges, and hypertrophy of the glandular structure of the nasopharynx. His pamphlet is interesting and instructive, and does not overlook one important fact — which is, that all deviations from what is often called normal do not require operative treatment.

233. Dr. Luckie gives accounts of a successful case of suprapubic lithotomy; of two cases of fracture of a cervical vertebra, with recovery; and of two cases of successful triple amputation after railway accidents These are all very interesting cases. The diagnosis in the cases of fracture of the vertebræ may be open to question; but certain of the symptoms undoubtedly point to the conclusion arrived at by Dr. Luckie.

234. This pamphlet consists of a medical report by Dr. Lloyd, and a surgical report by Dr. Deaver. The patient was a woman under Dr. Lloyd's care in the Philadelphia Hospital, in whom he diagnosticated a tumor of the spinal cord, and on whom he invited Dr. Deaver to operate for its removal. The operation consisted in removing the spinal processes and part of the laminæ of the third and fourth spinal vertebræ and passing an exploring needle through the dura mater. No tumor was found in the spinal canal; and the patient died on the fourth day.

The reports are interesting and instructive and the reporters are to be applauded for publishing a plain statement of the history of the case and the operation, although the result was so different from what they hoped for.

235. Dr. De Schweinitz, in this pamphlet, gives a clear and succinct account of the history of a case of optic neuritis, under his care, with some general remarks upon this interesting form of eye-disease and its proper treatment. His paper is instructive in pointing out the manner in which an attack of optic neuritis may begin and progress, and a careful reading of it might lead to recognition of such cases by general practitioners in time to secure for the patients the advice of an experienced ophthalmologist when it would be of the greatest service to them.

236. Dr. Palmer gives a remarkably fair and just review of the present status of the method of treating gonorrhœa by washing out the urethra from behind forward with an antiseptic solution He describes the method — not formally, but rather incidentally—gives the plan he finds most useful, namely, to combine the use of one of the usual injections with the "retrojection," and states the results which may be reasonably expected. His paper is very interesting and instructive, and may be heartily commended to the attention of our readers

237. This pamphlet contains the report of a meeting of the Chicago Medico-Legal Society in which the question of injuries of the spinal cord, such as are produced by railway accidents, was very fully and very ably discussed. An attempt was made to distinguish between the real and the false in cases of apparent injury in which no structural change can be detected. The paper and the discussion are both interesting and instructive and well worthy of careful study.

CORRESPONDENCE.

Artificial Stimulation of the Growth of Bone.

TO THE EDITOR.

Sir: I am obliged to your kindness, which induced you to send me the number of February 16 of your distinguished paper, with an extract of my discourse in the Berlin Medical Society "on the artificial stimulation of the growth of bone in men." In this extract you do not mention another method, which I first employed in men, and which for this purpose and aim in men, before me was not yet used; that is, the application of thick, steel pins, or needles (of different sizes, mostly two millimeters thick and from three to five inches in length) in the ends of the long bones nearest to the cartilage connecting the diaphysis with the epiphysis—as we call it "*Intermediärknorpel*" or (with Volkmann) "*Fugenknorpel.*" These steel nails (which must be nickled—*vernickelt*) must be applied under *strongest antiseptic measures;* the limb is then fixed on an iron splint or in a plaster-of-Paris bandage (*gypsverbana*); ice is applied and small repeated doses of morphine given for the pains. After 6 to 10 days the nails *sive* needles are removed under the same strong aseptic measures. A week or two later I apply the constricting rubber tube, the massage, the exercises and the nourishment, in which especially must be avoided lactic acid and the formation of this acid out of the nourishment (to avoid the starch-meal-containing nourishments and those which contain lactic acid).

The application of the steel needles is best done with an special handle, in which the needle is fixed by a screw. I bore the needle in the bone, then unscrew the handle, leaving the needle in the bone. The removing of the needle is done with the same handle, after having fixed the free end of the needle in the handle by the screw. Thus this work is done in the most careful manner without any disturbance and shaking of the bone.

The combination of this operation with the treatment reported also by you, gives a very successful increase of blood and a moderate but sufficient irritation in that part of the bone from which comes the growth and lengthening of the bone in youth. Success is to be seen much more quickly than without operating. But *all must be done very carefully.* According to this plan I treated three patients, with the best success. These are also reported in my paper. Now I have some more patients under treatment. In one case I had a lengthening of the femora of 5 centimeters (nearly 2 inches) in half a year; in others 4 centimeters, etc. We have, I think, in this combination an especially good measure to stimulate the growth of the bone in men—a measure without any danger in careful hands.

Please give these lines also to your readers.

Yours truly,

PROF. D. MAX SCHÜLLER.

Berlin, Germany,
March 4, 1889.

The Virginia State Medical Examining Board.

[A physician of this city who is very much interested in the passage of the bill to appoint a state board of medical examiners, which is now pending before the State Legislature of Pennsylvania, wrote to Dr. Dabney, Professor of Practice of Medicine in the University of Virginia, and Ex-President of the Virginia State Medical Examining Board, to learn the truth concerning certain charges of dishonesty and partiality made against that Board, which charges were contained in a letter to the *Medical Register* of Philadelphia, in its issue of February 23, from a Dr. E. L. Detwiler, and endorsed editorially by the *Register.* In reply to the inquiries made of him, Dr. Dabney sent the following letter, which shows that the Virginia State Medical Examining Board has endeavored to act honestly and impartially in all its examinations, and that the effort to have the graduates of Virginia Colleges exempt from the operations of the act was strenuously resisted by prominent members of the Faculty of the University of Virginia.]

MY DEAR DOCTOR:

Your letter and two extracts from the *Medical Register* were duly received. I had not seen these attacks upon the Virginia Medical Examining Board before, and I at once wrote to Dr. H. T. Nelson, who is now the President of the Board, to learn the facts.

I will take up the charges made in the *Medical Register seriatim.*

1. It is stated that the President of the Board (Dr. A. G. Latham, of Lynchburg, was then President) requested that a certain candidate be given "a nominal examination of ten minutes." Dr. Nelson tells me that the circumstances were as follows: a Dr. Blubaugh, who had practised in Virginia prior to January 1, 1885 (when our law went into effect), as *a member of a firm*

of physicians, asked whether he would have to stand an examination. The law was not explicit on this point, but Dr. Latham believed he was entitled to practise *without* an examination; but he advised Dr. Blubaugh to stand a nominal examination so as to comply technically with the provisions of the law. Subsequently, however, Dr. Latham reconsidered the matter and told Dr. Blubaugh that he must stand a regular and thorough examination.

2. It is stated that the returns "were altered" at a recent meeting of the Board. Dr. Nelson tells me that at the meeting in Norfolk in October last two negroes presented themselves, one a graduate of Howard University, Washington City, and the other a graduate of the Leonard Medical School for colored men, in Raleigh, N. C. One of these men had been registered three times before, and the other once before. At the meeting in Norfolk they did not reach the required standard (75 per cent.); but the Board made an exception in their cases, and licensed them to practise medicine in Virginia. The Board was induced to do this, Dr. Nelson tells me, by two considerations; one was that these men expected to practise in a section of country inhabited almost entirely by negroes, and where no white man could make a living; the second consideration was that they had spent all their means in acquiring what education they had, and therefore could not pursue their studies further at any medical school. It was the opinion of the Board furthermore that they were capable of doing substantial service to the persons among whom they proposed to settle.

3. It is stated that the object of the Medical Law in Virginia is to force students to attend the Virginia schools.

I am in a position to answer this question myself, without reference to Dr. Nelson, though the facts are familiar to him and any other member of the profession in Virginia who has taken any interest in the matter. I was the chairman of the committee of our State Medical Society appointed to present the "Medical Bill," as it was then called, to the Legislature. A proposition was made then by several members of the Legislature to exempt the graduates of the Medical Colleges of the State from examination, the argument used being that the number of students in attendance upon our State schools would thereby be increased. I opposed this proposition with all the energy I could command, and told my brother-in-law, Mr. Moon, who was the patron of the bill in the House, to have it defeated rather than to have such an "exemption clause" inserted. Subsequently, after the law had been enacted and the Board had been organized, a similar proposition was made. It was bitterly opposed by the Board, and I (as President of the Board) addressed a letter to Dr. I. L. Cobell, the senior member of the Faculty of the University of Virginia, and a similar letter to the Dean of the Medical College of Virginia at Richmond, asking if they desired the graduates of their respective schools to be exempt from the State examination. Both replied that they desired their graduates *to stand* the State examination; and Dr. Cobell wrote so forcibly and earnestly on the subject that his letter was of immense value to us and has been used with telling effect since. As a further evidence that the Board shows no partiality to the Virginia Medical Schools, I may state that 33 of our graduates have stood the State examination and 1 (one) has been rejected; and 57 graduates of the Medical College at Richmond have stood the examination, of whom 8 were rejected.

I do not know Dr. E. L. Detwiler, of Herndon, Virginia, who makes this charge of partiality toward the State schools as against the Board, but Dr. Nelson and I found, in looking over the Register kept by the Board the other day, that a man of that name and having the same post office, was rejected by our Board in April 1886, but passed his second examination some months afterward. Possibly it is the same gentleman.

I need not take up your time by giving Dr. Nelson's explanation of the apparent mistake in his tables, from which it appeared that three *different* graduates of the Medico-Chirurgical College had been rejected, instead of but one who was rejected three times. The apparent mistake was due to the way in which the tables were arranged.

I sincerely trust that you may succeed in getting the proposed law through your Legislature. The only way, it seems to me, to elevate the standard of medical education in a country like ours is to have in each State a Board of Examiners who shall *not be connected with any school* and who will *recognize no diploma*. This plan was proposed by Dr. I. L. Cobell of the University of Virginia more than forty years ago.

Very truly yours,

WM. C. DABNEY.

University of Virginia,
March 23, 1889.

Notes and Comments.

A New and Simple Method of Estimating Per Cent. of Fat in Milk.

In a letter to the Philadelphia *Ledger*, March 16, 1888, C. B. Cochran, Inspector of Foods, Pennsylvania State Board of Agriculture, says: To creamery men at least, if not to others, the most valuable constituent of milk is the fat. Hence has arisen within the past few years the custom of paying for milk prices dependent upon the per cent. of fat it contains. In many creameries throughout the country this custom was adopted just as soon as it was made feasible by the discovery of a simple and practical method of estimating accurately the fat in milk. There are two methods now in use among creamery men. In the first method, the fat is separated from the milk by means of an instrument called the lactocrite, and the per cent. found by measurement of its volume. In the second method, the insoluble fatty acids of the milk fat are separated and their volume measured. From this measurement and from the specific gravity of the milk is calculated the per cent. of fat. This method is commonly known as Short's method.

The chief objection to the lactocrite is its cost, which, when complete, is about $250. The method of Short requires from three to four hours' time, and gives results not so reliable as the lactocrite.

The method which we now, in outline, bring before the public, will be found, we believe, to combine the following desiderata—cheapness, simplicity, rapidity of execution and accuracy. The necessary apparatus consists of one 10-cubic centimetre pipette, two 5-cubic centimetre pipettes, one 10-cubic centimetre lipped test-tube, and the analyzing flasks, the number of which will depend upon the number of samples of milk to be analyzed. These flasks taper at the top into long, narrow cylindrical necks, so graduated as to read both volume and per cent. of fat. To the above apparatus it is desirable to add a good lactometer or lactodensimeter.

The method of analysis is as follows: Into one of the flasks drop 10 cubic centimetres of the milk to be analyzed, add five cubic centimetres glacial acetic acid and five cubic centimetres sulphuric acid. Stand the flask in water boiling hot, or nearly so, for 10 or 15 minutes, shaking it once or twice in the mean time. Then remove the flask from the hot water bath, allow it to cool, add from the test tube 10 cubic centimetres of ether, shake thoroughly so as to mix the ether with the contents of the flask. Allow the flask to stand for three or five minutes, then boil off the ether. When the ether is all evaporated a layer of clear fat is found floating on the liquid.

By the addition of hot water this layer of fat is now raised into the narrow graduated tube, which constitutes the neck of the flask, and its volume and per cent. there ascertained. The water used for the last named purpose should be nearly boiling hot, otherwise there is a tendency for the fat to adhere to the sides of the tube, and thus produce too low a result. By the use of hot water, however, there is little or no danger of loss from this source. This process seems to effect a complete separation of the fat from the milk, and, furthermore, the fat is free from every trace of casein, and can be very accurately read.

The fat of eight or ten samples of milk can be estimated by this method in about one hour, and I hope to be able, by changing the shape of the flask somewhat, so that the ether can be boiled off more rapidly, to shorten this time. The matter of the shape of the flask is now under consideration and will be settled soon.

Results obtained by me in the above described process agree closely with results obtained by Hehner's formula and by the paper coil process. This last named process has been officially adopted by the English Society of Public Analysts.

Bacteria in Milk.

The Berlin correspondent of the *Lancet*, March 9, 1889, says that it is intended to establish a bacteriological laboratory for the investigation of milk. The idea is due mainly to Dr. Hueppe, of Wiesbaden, who has for several years made a special study of the bacteria that appear in milk. He has definitively proved that lactic acid fermentation is caused by a special fungus, and butyric acid fermentation by another. Prazmowski, Liborius, Fuchs, and Neelsen have discovered other bacteria in milk, and their purely scientific researches, undertaken solely with a view to widening the limits of bacteriology, are now bearing valuable practical fruit. It is known that infant mortality is due largely to unwholesome milk, which can now be rendered harmless by sterilization. Further practical advantages are certain sooner or later to accrue from these investigations.

Massage in Pelvic Inflammation.

Dr. Semianikoff has employed massage in twenty cases of pelvic inflammation of a chronic character which had resisted other forms of treatment, and speaks very highly of the results obtained. All the cases were in Professor Slavianski's gynecological clinic in St. Petersburg. The cases in which the most marked effects were produced were those in which there were peri-uterine effusions of moderate dimensions. Chronic ovaritis, too, yielded to the same treatment. It should be stated that in some of the cases daily sittings for about three months were required to effect a cure. Of course the treatment was intermitted during the menstrual periods.—*Lancet*, Feb. 9, 1889.

Fatal Case of Cocaine Poisoning.

The *Lancet*, Feb. 9, 1889, says that an inquest was held at University College Hospital on Jan. 31, by Dr. Danford Thomas, coroner for Central Middlesex, touching the death of Charles Sidney Fletcher, who at the time of his decease was an inmate of the hospital. Fletcher was admitted under the care of Mr. Berkeley Hill, for disease of the urinary organs. From the evidence of Mr. John Creswell, house surgeon, it seems that it was intended to wash out the bladder with a detergent astringent solution, and to deaden the sensibility to the pain a solution of cocaine was to be first injected. The two prescriptions, the one for the cocaine and the other for sulpho-carbolate of zinc, were written on the same paper. The former simply directed that twenty grains of cocaine were to be dissolved in one ounce of water, and to it was appended the word "*statim*," without an accompanying verb to make the term intelligible. It was this defect which primarily led to the mistake which cost the deceased his life. The house surgeon wished to convey by the word "*statim*" that the solution was to be *dispensed* immediately. The dispenser, misled no doubt by the meagreness of the directions, misinterpreted it, and believing the solution to be a *draught* for the patient to take, put it in a measure glass and gave it to the nurse who waited for it. The latter administered it to the patient at once. It appears that upon writing the prescription the house surgeon put the paper on the table of the ward, and told the nurse to obtain from the dispensary the drugs ordered. When the nurse returned to the ward the house surgeon was engaged at an operation in another part of the building, or probably it would have chanced that he would have been consulted as to the correctness of the dispenser's reading of his prescription. Curiously, although the sulpho-carbolate of zinc solution was directed to be made into an *injection*, no intimation of the intended use of the cocaine solution was given. The fatal error was not recognized until the effects of the working of the cocaine became manifest. What the initial symptoms were is not known, for it was not until nearly an hour had elapsed that the nurse, hearing the patient making some unusual noise, had her attention drawn to him. It is said that there was some arching of the back resembling the opisthotonus of tetanus, and that there was a convulsive movement of the limbs. Consciousness was to some extent retained almost up to the fatal issue, since the patient, although apparently insensible, could be roused sufficiently to say, "I shan't," in answer to an injunction to do something. Death took place in about an hour after swallowing the cocaine solution.

The post-mortem showed tuberculosis of both lungs and of the right kidney. The left kidney had been entirely destroyed and its place occupied by the remains of the shrunken capsule.

Over-Pressure in Children.

In a note recently published by Professor Charcot on "over-pressure," the author asserts that intellectual or cerebral overwork does not exist in children under sixteen years of age. A child, he says, can make only the amount of intellectual effort of which he is capable. If he has programmes too overcharged to fulfil, he simply does not fulfil them; if one insists on cramming his memory with crude facts, no result whatever is obtained; but this does not in any way affect the brain of the child, the passiveness of which is complete, and the indifference absolute. On the other hand, according to the Professor, "over-pressure manifests itself only in youths above sixteen or eighteen years. It is characterized by a number of nervous troubles, principally by a pain in the occipital region, which extends down to the back of the neck, and goes up again in front of the ears. This over-pressure is seen in pupils of the superior branches of study, in men of letters who write much, in political men who are or who believe themselves to be overwhelmed with responsibilities, in men of business, etc., who lose their sleep, but never in the pupils of our *lycées* and colleges."—*Lancet*, Feb. 23, 1889.

Case of Chorea Major Associated with Formation of Fungi in the Pia Mater.

Prof. B. Naunyn reports this case from the medical clinic at Königsberg. The patient was a girl, 17 years old, who had had severe chorea since her eleventh year. On July 16, she died. At the autopsy there were found endocarditis and slight œdema of the brain and spinal cord. The pia mater in the neighborhood of the chiasm and in spots in the fossa (fissure) of Sylvius a peculiar brownish-red coloration as of deposited hæmatin. Microscopic examination showed that there were fine fibres in the pia, especially along the vessels, which proved to be fungi. According to Prof. Zopf, the fungus belongs to a kind between the *cladothrix* and *leptothrix*. Similar fungus-formation was found on the valves of the heart.—*Schmidt's Jahrbücher*, Jan. 15, 1889.

Therapeutics of Eczema.

Dr. Veiel, of Canstatt, says in the *Med. Correspondenz-Blatt d. würrt arztl. Landesver.*, that in acute eczema internal treatment is not indicated, while in chronic, widely distributed eczema arsenic is to be used simultaneously with external treatment. If chlorosis is present iron should be administered half an hour before meals and arsenic one hour after meals. Cod liver oil and regulation of the diet are very important in scrofulous eczema. For the itching of eczema, he uses chloral and bromide of potash internally.

The stage of the affection is of importance as regards treatment. In acute eczema all irritants are to be avoided. Where, as in children, baths are not entirely to be avoided, some mucilaginous substance should be added to them. All soaps are to be avoided. To diminish the burning and itching in acute, but not moist, eczema, Veiel recommends Unna's zinc paste:

℞ Oxide of zinc
Gelatin . . . . . āā ℥iv
Glycerine . . . . . f ℥viss
Distilled water . . . . . f ℥iss

To be warmed in a water-bath and applied with a bristle pencil.

After several days it is to be washed away with lukewarm water. In moist eczema the affected places are washed once daily and then the paste is again applied. If this proves ineffective, Veiel employs starch cushions, which remain cool and are often changed. If in universal eczema the paste is not borne starch is applied in powder, with which, if there is much itching, two per cent. of camphor is mixed. If this is of no service, the parts are washed with borax, or acetate of alumina, with some glycerine:

℞ Liquoris alum. acet. . . . . ♏ cl
Aquæ destil. . . . . f ℥iii
M.

or,

℞ Boracis . . . . . gr. liii
Acid. salicyl. . . . . gr. ivss
Aquæ destil. . . . . f ℥vss
Glycerini . . . . . f ℥i
M.

For extensive weeping eczema ointment-mulls and pastes are employed. If the scurf is dry and scaly, a five per cent. tannin salve is used.

In chronic eczema the crusts and scales are first loosened with soft soap, baths, or oil. The healing of the moist places is brought about as before. The addition of one or two per cent. of ichthyol is very serviceable. If the eczema still continues scaly, Lassar's paste is indicated, or tar with alcohol:

℞ Picis liquidi . . . . . ♏ xv
Alcoholis . . . . . ♏ xlv
M.

or tar may be added in the strength of one or two per cent. to the salve above mentioned. The employment of the latter on the hairy parts of the face and pubes is contraindicated, as in these places inflammations resembling sycosis are easily developed. If the eczema does not yield to the tar, pyrogallic acid and chrysarobin (in an ointment, from two to ten per cent. strength) is at times attended with success.—*Wiener med. Presse*, Feb. 3, 1889.

Charcot's Opinion of Professional Women.

M. Charcot, one of the Jury of the Faculty of Medicine in Paris, in complimenting a young lady who had obtained her doctor's degree, said that "women pass their examinations, when they do pass them, even more satisfactorily than men; but what will be always a bar to their success is that they have no real love of their proposed profession. What they aspire to is the first rank, the most prominent posts, the most lucrative offices; and what they dislike is the humble and unpleasant, but necessary, service of humanity such as is given by the hospital dresser." Curious, but precisely the same thing might just as correctly be said of men.—*Chemist and Druggist*, Jan. 5, 1889.

Medical Practice in Michigan.

A bill to regulate the practice of medicine in Michigan has been introduced into the Legislature. It provides for the appointment by the Governor of a board of six physicians to be medical examiners. Two are to be of the homœopathic school, two eclectics, and two regulars. All are to be graduates, but none can be connected with a medical college in any capacity. Any person practising medicine without a license from this board may be fined $100 or sentenced to jail for ninety days. All persons are regarded as practising who append M.D. or M.B. to their names, or direct, or for a fee recommend, for the medicinal use of any person any drug. Every person licensed must have attended three courses of lectures of at least six months each, and must be examined in the fourteen standard branches of medical practice. The examination fee is $10, and the license must be filed with the county clerk. The board can revoke a license for unprofessional or immoral conduct.—*Medical Standard*, March, 1889.

Cocaine in Teeth-Extraction.

In the St. Petersburg weekly *Rüsskaia Meditzïna*, No. 39, 1888, p. 623, Dr. I. S. Kolbasenko, of Kopal, writes that he resorted to Dr. G. Vian's method of local anæsthesia (*Therapeut. Monatschr.*, 1887, p. 502) in nine cases of teeth extraction, once in his own case. The method consists in injecting into the gum, both into its buccal and lingual surfaces, a solution of $\frac{4}{5}$ of a grain of cocaine in ten drops of a 2 per cent. aqueous solution of carbolic acid. The following noteworthy conclusions have been arrived at by the author. 1. In the presence of an inflammatory swelling of the gum, cocaine does not develope any pain-killing effects whatever, which may be explained by the well-known fact that infiltrated tissues lose their absorptive power more or less completely. 2. But when the gum is normal, *i.e.*, not inflamed, the injection is invariably followed in a few seconds by a local numbness, and in two or three seconds, never later than in four minutes, by a complete anæsthesia. The extraction performed at this stage remains always quite painless from the beginning to the end. 3. The injection, however, is constantly accompanied by a train of more or less pronounced general phenomena, such as giddiness, clouding of sight, acceleration of the pulse, and, later on, by a kind of drunkenness with talkativeness, exhilaration, etc., the symptoms being especially marked in anæmic and nervous persons. In the latter a genuine hysterical fit, with clouded consciousness, tears, etc., may supervene. 4. Hence in those susceptible subjects a due caution is necessary. 5. The best means for preventing and weakening the general symptoms are these: (1) the injection should be preceded by the internal administration of a wineglassful of rum or strong wine; (2) After the extraction the patient should be placed in a horizontal posture with his head hanging down; (3) inhalation of two or three drops of amyl nitrite should be resorted to.

National Association of Railway Surgeons.

The Annual Meeting of the National Association of Railway Surgeons will be held at St. Louis, Mo., on Thursday and Friday, May 2 and 3, 1889. Dr. W. B. Outten, of St. Louis, is the Chairman of the Committee of Arrangements. Any desired information can be had by addressing the Secretary, C. B. Stemen, M.D., Fort Wayne, Ind.

Pennsylvania State Medical Society.

The Fortieth Annual Meeting of the Medical Society of the State of Pennsylvania will be held in Pittsburgh, on Tuesday, Wednesday, Thursday, and Friday, June 4, 5, 6, and 7, 1889, commencing on Tuesday, June 4, at 9 A.M. The appointments for 1889 are as follows:

Address on Practice of Medicine, Dr. J. C. Wilson, of Philadelphia; *address on Surgery*, Dr. J. B. Roberts, Philadelphia; *address on Obstetrics*, Dr. Frances N. Baker, Media; *address on Mental Disorders*, Dr. Alice Bennett, Norristown; *address on Laryngology*, Dr. W. H. Daly, Allegheny; *address on Hygiene*, Dr. T. J. Mays, Philadelphia.

The Chairman of the Committee of Arrangements is Dr. E. A. Wood, of Pittsburgh, to whom all applications to read papers at this session should be sent *not later than April 15*.

The Secretaries of County Medical Societies are earnestly requested to forward at once complete lists of their Officers and Members, giving the post-office address of each.

All who desire Excursion Orders should notify the Permanent Secretary, Dr. Wm. B. Atkinson, at an early date, stating which railroad must be used.

NEWS.

—The Eighteenth Congress of the German Surgical Society will be held in Berlin, April 24–27.

—Dr. Adolph Bardeleben, Professor of Surgery in the University of Berlin, celebrated his seventieth birthday March 1.

—Dr. Charles F. Stillman, of New York, has been elected to a chair of Physical Examination for Life Insurance, which has just been created in the University of Vermont.

—Dr. John G. Womble, a prominent physician of Baltimore, died suddenly in that city March 13. He was graduated from the University of Maryland Medical School in 1871.

—Dr. Thomas Fitch Perley, Medical Inspector General during the closing years of the war, and a noted entomologist, died in Portland, Maine, on Thursday, March 21. He was 73 years old.

—The *Lancet*, Feb. 23, states that yellow fever is said to have broken out at Versailles, and to have numbered thus far four victims. It has been suspected that the germs of the disease have been carried there from South America in the plumage of parrots

—Mr. Henry Carter died recently in England at the age of 92 years. He is believed to have been at the time of his decease the oldest member of the Royal College of Surgeons of England. His death was caused by a fall which fractured his left hip.

—The Faculty of Medicine of Paris, upon the report of a committee composed of Professors Potain, Jaccoud, Grancher, and Straus, have decided to give the Lacaze prize of 10,000 francs to M. Malassez, Director of the Histological Laboratory of the College of France, for his investigations upon tuberculosis.

—The *Memphis Medical Monthly*, March, 1889, says of its midwives: "There are twenty-one of these persons. Seventeen of the twenty-one acknowledge their signatures with an X. They are an old set, as evidenced by the time of service in the capacity of midwife claimed by each—the average being twenty-five years and eight months."

—Dr. William H. Ford, President of the Board of Health of Philadelphia, states that the bill to prevent the sale of adulterated and impure milk was negatively recommended, owing to the opposition to a prohibition of the sale of skimmed milk. He also said that the Board had now taken the matter into its own hands, and that a relentless war would be carried on against dishonest milk dealers. The Sanitary Committee of the board has been instructed to take further steps to promote the passage of a milk bill.

HUMOR.

WEAK EYES.—A Knoxville, Tennessee, doctor advised a patient to use whiskey on his forehead every morning for neuralgia. Meeting his wife a few days after the physician inquired as to her husband's health. "He's no better," replied the lady. "But I told him to rub whiskey on his forehead," said the doctor. "True," answered the lady, "but John never uses it higher than his mouth."—*Cincinnati Lancet-Clinic.*

FREE MEDICAL ADVICE.—"Doctor," said a citizen, as he overtook him on the street, "what do you do in case of a gone stomach?"

"Well," replied the doctor, thoughtfully, "I've never had such a case myself, but I would recommend you to advertise for it, and then sit down in a large easy-chair and wait until somebody brings it back."

WHAT DID HE MEAN?—"I hope, Mr. Templecourt," said the lady, as she rose from the chair which had vibrated with her voice for an hour and a half, "that I haven't been taking up too much of your valuable time." "Not at all, Mrs. Chatty," returned the lawyer, glancing wearily at the pile of letters on his desk: "I assure you that this time has been of no value to me whatever."—*Puck.*

A STORY is going the rounds concerning the absent-mindedness of Byron, the playwright. A new play was running through the dramatist's head as he was walking through Pall Mall, when a friend stopped him and said: "I am in grief." "What is it?" asked Byron mistily. "I lost my father last week," said the man. "Too bad, too bad," said Byron, with an air of absent sympathy; "very sorry." Then he walked on and continued to think about his play. Three weeks later he happened to be again in Pall Mall, when the same man came up to him and said: "More misfortune." "Eh?" said Byron absently. "I have just lost my mother," said the man lugubriously. "Dear me!" said the dramatist petulantly. "You lost your father only a little while ago. What an exceedingly careless man you are."

PHYSICIAN DEPOT

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

AN INVALUABLE WORK
FOR EVERY PHYSICIAN AND DRUGGIST.

NEW (Sixteenth) EDITION,

THE UNITED STATES DISPENSATORY.

The Standard Commentary for more than Half a Century.

CAREFULLY REVISED AND REWRITTEN by HORATIO C. WOOD, M.D., LL.D., J. P. REMINGTON, Ph.G., and S. P. SADTLER, Ph.D., F.C.S.

ILLUSTRATED.

More than 800 pages of new material have been added and nearly 450 pages of effete matter have been dropped. One of the tests of the THOROUGHNESS OF THE REVISION is shown by the fact that none of the page numbers in the old edition correspond with those for the same subject in the new book.

☞ The work is for sale by all booksellers, or may be had direct of the publishers, free of expense of transportation, by enclosing the price. ☜

Price, in Cloth Extra, $7.00; Best Leather, Raised Bands, $8.00; Half Russia, Raised Bands, $9.00.

☞ Green Title Labels distinguish the Binding of the Sixteenth Edition. For facility of reference, Denison's Patent Index will be inserted for $1.00 additional to above prices.

715-717 MARKET STREET. PHILADELPHIA.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO.,

PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

NERVOUS DYSPEPSIA.[1]

BY EDWARD T. BRUEN, M.D.,

PHILADELPHIA.

ASSISTANT PROFESSOR OF PHYSICAL DIAGNOSIS IN THE UNIVERSITY OF PENNSYLVANIA, AND PHYSICIAN TO THE PHILADELPHIA AND GERMAN HOSPITALS.

I shall bring before you only one case this morning, not so much for the lessons which may be drawn from the study of the case in itself as for the purpose of describing the method of clinical study which should be pursued in the analysis of the symptoms, especially by means of certain chemical tests which have been recently suggested as very useful in such cases.

Dyspepsia, it is well known, is a term like albuminuria, or dropsy, or anemia; it is a name which may embrace very many totally different pathological conditions.

For our purpose we may divide dyspepsias into three groups: (1) those in which there is a lack of secretion of hydrochloric acid; (2) those in which there is an increased secretion of hydrochloric acid; (3) those in which there is a want of nerve power, or a sympathetic nervous dyspepsia attended by the formation of a variable amount of hydrochloric acid.

Cases which belong to the first group are frequently those of gastric carcinoma; not because this process exerts any mystical influence to prevent the formation of HCl, but because the later stages of carcinoma of the stomach are attended with atrophy of the gastric follicles. The constant presence of HCl in anything like normal quantity is the best evidence which can be given that gastric carcinoma does not exist. There are, however, other cases of gastric disorder in which HCl is deficient. In the amyloid process, and in circulatory diseases which favor portal repletion the secretion of HCl is much reduced. In chronic gastric catarrh the same process of reduction in the elaboration of HCl occurs. The form of dyspepsia associated with chronic gastric catarrh must

[1] Delivered at the German Hospital.

therefore be differentiated from malignant disease.

The dyspepsias of the second group include chiefly gastric ulcer. Indeed gastric hyperacidity is believed to be a predisposing cause of gastric ulcer. This hyperacidity may not only arise from the overproduction of HCl, but lactic acid, which exists in the stomach during the earliest stage of the digestive process, and is frequently formed during the digestion of food by fermentation, may also be a factor in causing the hyperacidity which so commonly precedes the development of gastric ulcer. Various other organic acids may be formed during the process of faulty digestion, but the presence of the others does not so commonly antedate gastric ulcer as does the excess of HCl.

The third class of dyspepsias includes the cases which are represented by the patient we have before us at this time. This form of the complaint is often met with in factory girls, or those who work in shops. These persons are apt to be confined too closely, have little out-door exercise, often eat improperly, and generally use tea and coffee to excess, or eat coarse food in large quantities, or hurriedly. Such persons are especially predisposed to dilatation of the stomach, which may render their dyspepsia really incurable.

This dilatation occurs because of the constant accumulation of gases formed during the process of fermentation of food in the stomach. This form of dilatation may be also traceable to regurgitation of gases from the intestine, in certain cases of intestinal indigestion, so that the stomachic indigestion is secondary. All the forms of dilatation of the stomach mentioned might be denominated functional, to distinguish them from the forms of dilatation secondary to pyloric obstruction directly dependent upon cancer, or chronic inflammatory pyloric thickening after ulcer, or obstruction dependent upon the pressure of some tumor adjacent to the pyloric orifice.

A chemical analysis of the gastric contents should be instituted when practicable at the outset of the examination. If possible the patient's stomach should be washed out in the evening, and on the following morning a test-meal should be given consisting of an egg with bread and butter, and some hot milk, water and sugar as the beverage. In an hour after the test-meal a soft flexible tube, eighteen or twenty inches long—that is, a tube one-third or three-eighths of the length of the body—should be introduced into the stomach. The tube may be lubricated with milk, and the patient can learn to assist in the introduction of the same by swallowing efforts. Light pressure over the stomach may then be made, and with the effort of regurgitation on the part of the patient about one ounce of the gastric fluid can be brought up. If this method of obtaining the contents of the stomach fail, the stomach-pump may be used. The introduction of the tube will often occasion vomiting. The gastric contents being obtained they should be filtered, and Uffelmann's test employed. This consists of a four per cent. solution of carbolic acid with four drops, or sufficient tincture of the chloride of iron to produce a steel blue color. The filtered gastric fluid should be dropped into the solution very slowly, a yellow color being produced by lactic acid, and decolorization in the presence of HCl. Since it is possible for decolorization to be caused by other acids than HCl, Uffelmann's test should be reserved for lactic acid, while for hydrochloric acid Günzburg's test should be used. This consists of fifteen grains of vanillin and forty grains of phloroglucin mixed in one ounce of alcohol. With a trace of mineral acid, it produces a yellowish-red color. By dropping some of the solution into the filtered contents of the stomach, the HCl present will form a precipitate of bright red crystals. If the proportion of mineral acid is very minute, equal quantities of the solution and juice should be employed, and it will be necessary to evaporate the liquid slowly in a porcelain crucible. A deposit around the edges of fine red crystals will then be obtained. Heat should be applied with the spirit lamp, care being taken that the liquid that is testing does not boil. When the gastric liquid contains considerable quantities of albuminates or peptones the isolated crystals are not observed; but the bright coloring persists and the crucible is covered with a mixture composed of albuminates and fragments of crystals.

For clinical purposes the phloroglucin-vanillin test is perfectly reliable, though Faucher[1] concludes from some experiments with eggs of various degrees of freshness—prepared by mixing their whites with a given weight of distilled water—that though new-laid eggs give a negative reaction with the phloroglucin-vanillin, eggs five days old become rose colored; three eggs of doubtful freshness gave an intense, dark-red color;

[1] *Journal de Méd.*, Paris, August 12, 1888.

in short, the intensity of the reaction was in proportion to the age of the egg, which contains an increasing quantity of sulphuric acid as it becomes stale. Dr. F. Spaeth has devised a very simple apparatus for testing the presence or absence of HCl. He takes a small bullet (No. 6) and wraps about it a silk thread (No. 1), which he has previously soaked in a 0.015 per cent. watery solution of Congo red. To this is fastened also a small piece of elder-pith which has been soaked in blue litmus paper. The whole is attached to a long silk thread. The bullet and pith-ball are swallowed and allowed to remain in the stomach for a minute, and then drawn up. Any acid present turns the litmus pith to red, while if free HCl is present it turns the Congo-red thread a blue color. Acetic and butyric acids can be detected by the smell, especially after the fluid is shaken with ether, and the ethereal residue evaporated.

The patient whom I bring before you this morning is a woman, 28 years old, who complains of pain over the epigastric region, loss of appetite for the last two years; she has vomited blood once. The patient has lost forty-five pounds in weight, and is quite anemic—weighing now only one hundred and eight pounds.

Malignant disease may be set aside as unlikely to be present on account of the age of the patient. Gastric ulcer can be excluded because the pain is diffused over the whole stomachic region. Vomiting of blood has occurred only once. Localized tenderness is absent, and vomiting has been only an occasional not a constant symptom. But the analysis of the gastric contents shows a normal proportion of HCl, and such an analysis is a very helpful measure in the diagnosis.

I have prescribed for this patient:

℞ Ext. belladonnæ . . . . . gr. i
Argenti nitrat. . . . . gr. ii *vel* iii
Fiant pil. No. xii.

Sig. One pill 15 minutes before each meal.

The diet should be Malted Milk, as made by the Racine firm, or Carnrick's Soluble Food. Very carefully watched these preparations may be used to represent milk, but the patient should be weighed every week, to note any gain or possible loss.

This treatment has been successful in the present case. We have cautiously added first slightly boiled eggs, then meat broiled, then well-baked bread. Milk itself can be very rarely used in these cases, since it is liable to cause vomiting. It is for this reason that the foods named are so valuable as *temporary* substitutes for milk. I say temporary, since I would never regard an artificial preparation as fully representing standard milk; but they are of great value in bridging over a certain period of time. When neither milk nor these substitutes I have mentioned can be tolerated, one may resort to broiled meats with *zwiebach*, or toasted bread. I have no doubt that attention to the diet will suffice to cure this patient; and it must be remembered as a cardinal point in these cases never to give more food daily than can be digested.

February 1.—This patient has been discharged, having gained in weight fifteen pounds and nearly regained her natural appearance as to complexion. At present the patient has no symptoms of gastric indigestion. It will be necessary for her to observe the injunctions to be careful of her diet for some months to come.

It will now be possible to begin with the series of remedies calculated to reestablish the crasis of the blood, such as arsenic in small doses, iron, and the like. I would simply remark that it is well to give these remedies for a long time, and therefore a small dose is very desirable. I usually give at this stage of the treatment some nux vomica, and possibly zinc as a nerve tonic, as in the following pill:

℞ Acid. arseniosi . . . . . gr. ss
Ferri sulph. exsic. . . . . gr. v
Zinci sulph. . . . . gr. iii
Ext. nucis vomicæ . . . . . gr. v
Ext. gentianæ . . . . . gr. xxx

M. Ft. pil. No. xxx.

Sig. One pill 3 times a day.

In closing, I would call attention to the fact that I employ pepsin but little, while I lay stress on the fact that dietetic treatment is all important. Pepsin may be used as an adjuvant to diet, but not as a principal mode of treatment. The effect of acids and alkalies is very doubtful in cases of chronic nervous dyspepsia. It is said by some that they precipitate the mucus and in the long run lessen the formation of HCl and the peptic ferment. Alkalies are said to dissolve mucus, and to promote the secretion of HCl and the peptic ferment. My own opinion is that both modes of medication are adapted only to temporary use, and that in cases of prolonged functional dyspepsia they may even be injurious.

—Prof. Wilhelm Henke has accepted the Chair of Anatomy in the University of Gratz.

COMMUNICATIONS.

FLAT-FOOT: A NEW PLANTAR SPRING FOR ITS RELIEF.

BY A. SYDNEY ROBERTS, M.D.,

FELLOW OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA, EX VICE-PRESIDENT OF THE AMERICAN ORTHOPÆDIC ASSOCIATION, ETC., ETC.

Among the most distressing and painful deformities of the lower extremity, which the orthopædic surgeon is called upon to treat, cases of flat-foot stand foremost. I should not have ventured to speak of this very common deformity, did I not think that its importance is often overlooked, and that in many instances it is a source of much confusion regarding its etiology, diagnosis and treatment to those who have not had many opportunities for studying the disease.

As a rule the ordinary forms of club-foot are unattended with pain; this symptom entering only secondarily, either as a result of pressure from walking in the deformed position, or from the faulty mechanical appliances used to correct the deformity. In the form of talipes under consideration, however, pain plays an important part, and with this the disability produced is often so extreme as to render the patient unable to pursue his ordinary occupation. Thus, in addition to the usual end to be attained in the treatment of deformities of the feet, namely, the restoration to the normal form of the foot, we have another and more practical object, demanding our utmost attention and study, and that is the preservation of the means of livelihood to those who are unfortunately afflicted with flat-foot.

Like other forms of talipes, flat-foot, or talipes valgus, may be a congenital or acquired malformation, but it is very rarely found at birth to such an extent as to be considered pathological. On the other hand the acquired forms of valgus, taking all the varieties collectively—whether occurring as simple flattening of the arch, as secondary to rachitis, as the result of infantile spinal paralysis, or those of the inflammatory type—talipes valgus probably occurs most frequently of all the distortions of the feet.

It may be well, in this connection, before proceeding to an account of the etiology of talipes valgus, to give a brief account of the normal mechanism of the foot and of the plantar arch. All of that portion of the lower extremity situated below the tibio-tarsal articulation enters into the construction of the foot, and in the adult has the form of an arch, with its convexity or dorsal surface above and its concavity or plantar surface below. At the highest point of this arch, which is formed by the astragalus, the weight of the body is received and transmitted; receiving the weight on its trochlear surface from the tibia, and transmitting it through the so-called pillars of the arch. Of these there are two, the anterior one composed of the scaphoid, three cuneiform and the three inner metatarsal bones, being the longer, less oblique and more elastic. The posterior pillar, formed by the os calcis, is shorter and thicker, its concavity being directed inward, and it is less elastic than the anterior one. The astragalus, therefore, may be regarded as the keystone of the arch, but it differs in certain respects from the keystone of the ordinary arch. Whilst its anterior surface by its opposition to the concave posterior surface of the scaphoid fulfils this requirement, posteriorly it rests upon and overrides the os calcis. Hence, this weak point in the arch has to be supplemented, so to speak, and this is accomplished by the soft parts, the interosseous ligaments, passing between, and binding together the bones, the calcaneo-scaphoid ligaments arising from the inferior surface and forepart of the os calcis, and passing to the posterior and under part of the scaphoid bone, thus giving direct support to the head of the astragalus. Again, we have a secondary arch, supporting the primary one. This is formed by the outer part of the os calcis, the cuboid, and the two outer metatarsal bones, this supplementary arch being supported by the calcaneo-cuboid ligaments, whilst the strong plantar fascia extends between and acts as a brace to the pillars of the arch. It must not be forgotten that while an arch has ordinarily to receive weight only in one direction, in the case of the foot the direction of the weight is continually changed by the various positions assumed by the body in its movements. Thus, while in the standing position, the weight would fall chiefly on the astragalus and be directly transmitted to the two pillars of the arch; in walking, running, dancing, etc., involving as these movements do the different parts of the foot, the weight is constantly shifted, and consequently the ligaments and muscles of the foot are called upon to reinforce the arch by their action. Added to this there is the mobility of the

tarsus, and this mobility is the greatest just where the greatest strain falls, namely, between the astragalus and scaphoid. The muscle principally called upon in this connection is the tibialis posticus, whilst the inner part of the calcaneo-scaphoid ligament is chiefly engaged in resisting all extra strain.

It will be easily understood then, that, associated with the different complex movements alluded to, involving as they do the raising (flexion) and placing of the foot on the ground (extension), that on the resistance offered by the tibialis posticus, and calcaneo-scaphoid ligament, and upon the help thus given to the arch, depend the conservation of the form of the foot. Again, the normal curves of the foot give a certain amount of mechanical advantage in the distribution of the superincumbent body weight. Thus, in flexion, the two curves of the foot, the larger with its concavity downward, and a lesser one along the inner side of the foot with its concavity outward, are increased. On the other hand, in extension, as when the foot is firmly planted on the ground, both these curves are diminished and the foot flattened. It is evident, therefore, that any cause operating to weaken those tissues, which, by their aid, serve to strengthen the arch, will cause a permanent extension of the foot, with obliteration of the natural curves. Thus, in occupations requiring continued standing or walking, or the maintenance of a given position for a long time, these structures become overtaxed, and as a consequence do not afford the proper accessory support to the arch; there exists a condition of permanent extension of the foot and sooner or later, depending on the constitution of the individual, flat-foot follows as a consequence of this abnormal strain.

The morbid anatomy of flat-floot, or spurious valgus, shows differences according to the etiology of the given cases. Thus, in the congenital variety very few pathological changes are noticeable. The external appearance of the foot shows a decided lowering or flattening of the normal arch, with the inner margin of the foot depressed and closer to the ground, whilst the outer border is raised, and the anterior part of the foot everted. Sometimes in these congenital cases there is a marked degree of equinus associated with the valgus, and when this occurs, there is decided contraction of the calf muscles. In the congenital form of valgus, there is not much displacement of the bones of the foot, the principal changes consisting of the elevation of the tuberosity of the os calcis, while the astragalus is pushed downward and forward, and is seen as a prominence on the inner side of the foot, with the rotated scaphoid bone, which is also prominent. There is a slight rotation outward of the cuboid bone, and the malleoli are depressed, being found on a lower plane than normal. The weight of the body coming on these disturbed relations is not properly received and transmitted, and, as a consequence, the strain becoming too severe on those tissues which serve to assist the arch, there is a resulting stretching of the ligaments on the plantar and inner side of the foot. Thus, the calcaneo-scaphoid ligament especially, which bears the brunt of resistance to displacement and is constantly called upon in this connection, becomes relaxed. In the congenital form, although the muscles show few changes, with the continuance of the affection there often ensues a marked contraction of the peronei and calf muscles, the foot then taking the form of an equino-valgus. With this there is often found a contraction of the extensor longus digitorum, the extensor pollicis, and the abductor minimi digiti, with slight alterations in the relations of all the tendons of these muscles.

The forms of flat-foot which deserve most of our attention will come under those found in the acquired variety, and these are the cases which, from the unusual suffering and disability they occasion constitute a large and important class. They have been variously called "splay-foot," "spurious valgus," "inflammatory flat-foot," "tarsalgia of adolescents," etc. In children the acquired form of valgus usually met with is the result of a poliomyelitis anterior, and in this condition the anterior tibial and adductor muscles are usually the paralyzed ones. At times, as in the congenital form, there is a coincident contraction of the calf muscles, rendering the deformity a compound one, and we have a talipes equino-valgus. It is also found very often associated with knock-knee and bow-legs, as a mechanical result of these deformities, especially in rachitic subjects. Rachitis itself is a very prolific source of this deformity, while as a symptomatic condition in ankle-joint disease, after injuries and burns of the foot, and following rheumatism, flat-foot is of frequent occurrence.

Each one of these causes must be made out and its relations to the deformity closely studied, but the limit of this paper is too

short to give an extensive account of each variety. It is the condition variously named as already stated, that I wish to emphasize particularly.

While to the experienced orthopædist flat-foot is not especially difficult of detection, to one who has not seen many cases it frequently presents puzzling symptoms. Thus, it is frequently mistaken for neuralgia, rheumatism, and even for chronic osteitis of the tarsal bones, and I have had patients who have been treated for all these conditions before the real cause was diagnosticated. They are met with generally at the period of adolescence, although I have had several cases in which the patients were between forty and sixty years of age. In occupations necessitating long continuance of one position, as is the case in bakers, machinists, clerks, waiters, weavers, or in those vocations which compel constant and fatiguing motion, as in soldiers, the deformity happens frequently. Growing boys and girls, especially those of a languid disposition with an especial tendency to the accumulation of adipose tissue, are especially liable to this painful trouble. Certain races seem prone to this affection, namely, the negro and the Jewish races.

The gait and attitude of patients suffering with this trouble are characteristic and easily recognized. They have a heavy, dragging gait, the knees being bent, and the feet are placed in a careful, gingerly way on the ground, so that all the weight possible shall be kept from the tender part. When such patients step on an uneven surface the pain complained of is of an excruciating nature, and walking or standing is avoided as much as possible. The patients are easily tired and have an anxious expression of countenance, the general condition sympathizing to such an extent with the local trouble, that, in certain instances, the nutrition of the patient suffers very markedly. This is not difficult to understand when we reflect that, occurring as it does in young people generally active, and at a time of life when the desire for exercise and enjoyment is at its height, the enforcement of comparative idleness by the pain experienced prevents the proper completion of those functions which give the system at large its elasticity and tone.

The morbid changes found in the acquired form of flat-foot, are those which are found associated with the special etiological factors entering into the production of the deformity. For a long time it was supposed that the painful variety, in which we are especially interested, was due to an osteitis, but no absolute evidence of an inflammatory lesion, such for instance as that seen in the head of the femur in *morbus coxarius*, has been found. Still, I have seen cases in which, on rotation of the tarsus, marked reflex spasm of the abductor muscles was occasioned. If any osteitis be present, it would seem to me to be of the nature of dry, or caries sicca. In none of the cases that I have seen have there been evidences of suppuration, the local symptoms at times showing swelling, especially below the malleoli, with a semi-fluctuating feel; but heat is generally absent. On the contrary the feet of flat-footed people are, as a rule, cold, and have a peculiar, dark-blue look, as though the venous circulation was badly accomplished. The appearance of the bones is such that pressure in the deformed position would amply account for them. They are not especially altered in their relative positions, although, with the gradual falling of the arch, the astragalus becomes slightly displaced downward, the scaphoid and internal cuneiform bones being brought to a lower plane than normal, and nearer the ground. It is at the inner side of the foot where the astragalus and scaphoid show prominently, that, as a rule, the greatest amount of pain is experienced; but the location of the pain is by no means constant, the transverse tarsal joint, the metatarso-phalangeal articulation, and even the calcaneum being at times the seat. With the continuance of the abnormal pressure and the bony changes due to it, there is seen a gradual destruction of the normal arch. The abductor muscles begin to contract strongly, while the adductors are in a condition of functional paresis, and thus added to the flattening of the foot we have abduction, and a constant condition of extension; and if the contraction of the abductor muscles be maintained the outer edge of the foot is raised and does not touch the ground. In the extreme degrees of the affection the instep becomes totally obliterated through the loss of the convexity of the arch, and the internal malleolus especially becomes more and more prominent, and is seen with the protuberant astragalus and scaphoid bones as a prominence on the inner side of the foot.

In this condition, I have found, taking the medio-tarsal joint as a base line of measurement, and erecting upon this a perpendicular corresponding to the long axis of the os calcis, that the angle of internal deflection is reduced from twelve degrees in

moderate cases to five degrees in severe ones. From an examination of severe cases I have ascertained the average deviation from the perpendicular to be about eight and two-tenths degrees.

The prognosis in cases of flat-foot depends in a large degree on the causes which occasion the deformity, the surroundings of the patient, and the time when he comes under treatment. In the congenital form of the disease, when it is not of great severity, the prognosis is usually a favorable one, but the severer cases, and those which have been allowed to go on for a long time, are usually more resistant, and often necessitate protracted treatment. In the acquired form, occurring as it usually does in the poorer classes, although the wealthy are by no means exempt, and being mostly met with in those who are dependent for their support on their vocation, the prognosis is not so favorable, many of these cases not coming under treatment until the pain becomes excessive, and the deformity far advanced. Still, where the hygienic and other surroundings can be improved and the patients placed under favorable conditions, and when the disease is not the result of incurable paralysis or of chronic joint lesions, I know of no disease in which so much can be done for the relief of pain, and in which such gratifying results can be accomplished, although much time and patience may be necessary for the removal of the deformity.

Concerning the treatment of flat-foot very little need be said regarding the congenital type of the deformity. When seen shortly after birth the patients may be successfully treated by manipulations alone, these having for their object the carrying of the foot to a more inverted position. To retain the advantage gained by these movements moleskin adhesive plaster (Maws), with a roller bandage may be employed to draw the foot into the varus position. When the deformity is more severe, and the child older, external splints of a simple character, composed of tin, gutta-percha, or hatters-felt may be employed. These are moulded to the part, and a gradual inversion of the foot accomplished. Should contractions occur, which cannot be overcome by the use of the simple means mentioned, tenotomy of the peronei and extensor longus digitorum becomes necessary. Should the tendo Achillis be contracted this will also have to be cut. These operations, however, are best divided into two stages, the peronei and extensor longus being tenotomized first, and the tendo Achillis subsequently. Massage and electricity to the weakened tibial muscle may also be resorted to with the greatest advantage. When the child is old enough to walk, a simple support, consisting of two lateral uprights, connected with a band to encircle the calf, and with an inner pad corresponding to the axis of the astragalo-scaphoid articulation, and attached to the bottom of the shoe, may be used.

The forms of flat-foot which we shall be called upon to treat frequently are those which belong to the acquired variety. Here our treatment will, of course, be governed by the cause producing the deformity, and by the amount of pain and deformity. I have, already, in discussing the etiology of the disease given a brief account of the different causes operating to produce flat-foot, and will not dwell at length on the differentiation of these causes, but simply remark here that any constitutional causes or diatheses—whether strumous, rachitic or tubercular—should receive careful attention. Neither will it come into the province of this paper to discuss those extreme instances of valgus which, having been neglected for years, present so much deformity that nothing but exsections of the displaced tarsus will suffice for a restoration to a useful foot. The symptomatic valgus seen in the course of ankle-joint disease or osteitis of the tarsus, generally yields to the treatment employed for the primary lesion.

It is to the inflammatory form, so called, that I will place especial stress in the matter of treatment. I have already alluded to the difficulty of obtaining *rest* for these cases, owing to the fact that they for the most part occur in the working classes, where daily labor is necessary for their support. Where it can be done the removal of the patient from all employment suffices, especially, in beginning cases, to promote a rapid cure; but even in these cases some support to the weakened arch is called for. This has been accomplished in several ways, either by inserting pieces of leather, pads of different material and construction, steel-tempered bars, and springs on the plantar surface of the foot.

While relief can undoubtedly be afforded by these means, there are objections to their use; chief among these being the expense of especially constructed shoes and the introduction of these various contrivances. Of all those mentioned, however, I have had the best results from the use of tempered springs so made that the convexity of the spring shall be at that point where the arch

of the foot is most flattened. These I have had made to extend from the middle of the os calcis to the base of the metatarso-phalangeal articulation, and their object is to supply an artificial arch for the foot. They have, however, to be inserted as a shank into the shoe, and this necessitates the construction of a special boot, and oftentimes the making of a special last for the patient. Again, being very narrow they do not, when there is extreme flattening, give the desired amount of support, patients often feeling the necessity for more pressure than can be given by them. I am indebted to Mr. Arthur H. Lea for an improvement on this spring, and it gives, undoubtedly, the best support of all the contrivances I have used, or am acquainted with.

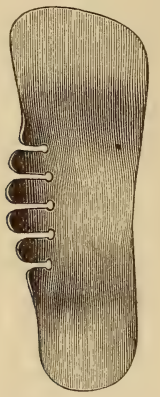

Fig. I. Upper surface of spring.

The artificial arch illustrated in the cut is made of tempered steel. An outline of the patient's foot is first taken, on stencil-board, the tracing being extended upward on the inner side of the foot. The elevated portion, corresponding to the depressed arch of the foot, can be tempered to the extent required by the particular case. The lateral pressure brought to bear by the elevated flanges is such, that, whilst giving support to the arch to a certain extent, the artificial arch also prevents further displacement of the astragalus and scaphoid. Again, in place of giving only a limited amount of support to the inner side of the foot, this appliance supports the foot as a whole. The objection argued against the narrow spring is entirely avoided by the use of this one. It can be placed in any shoe and changed at pleasure. In most of the cases in which I have used it the spring is simply inserted into the shoe without any fastening whatsoever. The transition from absolute disability to comparative freedom from pain which the use of this simple contrivance affords is surprising, and it is all the more gratifying from its simplicity and easy adaptability. Where the disease has lasted for a long time, I sometimes combine with it the ankle support

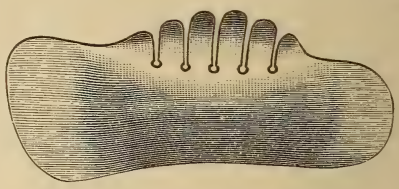

Fig. II. Under surface of spring.

mentioned, and it often serves as a valuable adjuvant in cases in which the muscles and ligaments are fatigued from long use in the deformed position.

I cannot close these remarks without enjoining the necessity of proper massage and electricity to the weakened parts. Much good also may be done at times by the use of rubber bands, especially in those cases in which the tibialis anticus is in a paretic condition. Concerning the use of plaster of Paris for the *redressment* of the foot, I would simply say that the chief objection against its use lies in the fact of its compelling the patient to keep his bed, and so depriving him of the benefit of fresh air and sunlight—both good adjuvants to the other treatment recommended.

COMPLICATIONS FOLLOWING ABDOMINAL SECTION.[1]

BY J. M. BALDY, M.D.,
PHILADELPHIA.

The attention of surgeons, in the past and at present, has so commonly and almost exclusively been called to the perfection of the different abdominal operations, that the possible complications which may follow have been lost sight of, or, if noticed at all, they are kept locked up in the bosom of the individual himself, and the profession at large hears and consequently knows very little about them. In consequence of this, medical men are continually running across these patients, and are having their faith in the value of the original operation shaken. Most men go into an operating room, see the operation, have a pathological specimen shown them, and then go away, satisfied as to the justifiability of the operation and confident as to the results. They may or

[1] Read at the meeting of the Obstetrical Society of Philadelphia, March 7, 1889.

may not see the patient several times during the treatment, but are generally satisfied with an inquiry as to how the patient is progressing, and finally have the satisfaction of hearing that she is well and has been discharged. The case is probably reported as cured to some society or medical journal, and thus the favorable statistics are swelled, and inexperienced and untrained men are led into attempting the operation, usually with the result of sacrificing several lives, before they are frightened off.

It is about time for surgeons to look at and seriously study some of the dark sides of abdominal surgery; for a dark side it certainly has. Our results, as far as removing disease is concerned, are about perfected; let us now turn some of our energies into preventing or alleviating some of the after-complications, which are in many cases as bad as the original disease itself. They do not probably cause such immediate danger to life, but produce symptoms just as hard to bear, as far as the patient is concerned, and to her belief, fully as bad at times, as her former trouble.

When I first began to give special attention to gynecological surgery, especially the abdominal variety, I was considerably worried that my cases did not always run as smooth and uncomplicated a course as I had been led to believe that those in the hands of my friends and others did. That they were not perfectly well when they got up, and came to me sometimes for weeks, complaining of one thing or another, was a source of great mortification to me. And finally, I began to find that troubles continued and others appeared, which it was extremely difficult to control. At first, supposing that I was the only one so afflicted, I thought there must be something radically wrong, either with my operations, or with my handling of the case afterward; and yet I could not reconcile these thoughts with the fact that I usually had the very best of assistance at the operation, and the constant advice of most competent men in the conduct of the after-treatment. Now I am constantly seeing and hearing of cases with troubles similar to my own, and also some with complications I have never personally met with. These cases are by no means confined to the practice of any one man, or any class of men, but represent patients of nearly every prominent operator in this city. Nor do I think that these results are confined to Philadelphia, but that they will be found wherever abdominal surgery is practised.

To consider fully the causes, prevention, and cure of these complications, is beyond the scope of this paper; my object being simply to call general attention to their frequency and to make a few remarks on the most common of them. Some of the subjects have been, from time to time, noted by other surgeons, and have been called to the attention of the profession, only to be dropped, almost as if they were subjects not to be handled and publicly discussed. Among the most frequent of these might be mentioned: hernias; simple fistulous tracks; fecal fistulas; pain, pelvic or abdominal; œdema of the lower extremities. I have seen many patients suffering from all of these troubles, and have had some of them follow in my own practice.

Holmes has found that he had thirty per cent. of hernias following his operations. Now as these cases were for the most part hospital patients, he could certainly not have kept track of them all, and so if the whole truth were known the per centage would be much higher. It would seem, at first sight, that a patient developing a ventral hernia would return for treatment; but not so, for in my own experience, with the exception of one patient, none of them ever reported, and I only discovered their existence from outside information. Thirty per cent. is, I think, a fair average of hernias following section. Most of the operators, with whose work I am familiar, have, I am confident, almost if not quite that proportion. I know of many cases in this city, of which the operator himself is not yet cognizant. Now a ventral hernia is by no means a harmless thing. I can recall women who suffer almost as much from the presence of the hernia as they did from the original disease—in fact more so; one case I know of had originally a small unadherent ovarian cyst, found in the course of a general examination, and which gave her few if any discomforts; she now has a good-sized ventral hernia, from which she suffers considerably. These hernias constantly tend to increase in size, and when the woman is one who must be on her feet constantly, carrying heavy burdens, lifting heavy weights, or in fact doing anything which will increase the tension at the abdominal opening, the result must invariably be a rapid enlargement of the protrusion, with all the accompanying distresses. There is no good reason why some of these hernias should not eventually, from various causes, become strangulated, and require a second and more serious operation; this has indeed actually occurred. The mere protrusion and displacement have

caused so much trouble that an operation has been devised for the closure of the opening.

The causes of hernia have been somewhat a matter of dispute; some contending that the drainage tube is most at fault, while the advocates of the tube repudiate that idea. Then again improper suturing is charged with the results. Whatever the cause, the lesion is certainly a lack of union of the muscular tissues and of the deep fascias; the remedy is plainly that of securing perfect apposition of the edges of these tissues. Time is frequently a most important element in an operation, and there is no need of wasting it by passing a separate row of sutures, in the peritoneum itself, as has been advocated and practised in some of our neighboring cities. The peritoneum always unites, and does so in a very short time. As far as I know, it has never failed to do so, excepting in those cases in which the whole incision failed. The hernia is always found to have a covering of skin, superficial fascia and peritoneum. It seems to me that a continuous catgut suture of the muscles and deep fascia is all that is needed, beyond the usual all-the-way-through suture. I can recall a case in which the presence of a hernia, by demanding an operation for its closure, resulted in the death of the woman.

This city now contains a large number of women with fistulous tracks in their abdomens. Some of these have followed the use of drainage tubes and others have been produced by abscesses that have ruptured through the incision, leaving a track which has never closed. The extra-peritoneal method of treating the pedicle in hysterectomy is a very frequent cause of fistula. The length of time it takes the clamp to come away is often so great as to leave an opening, which constantly discharges pus—in small quantities it is true, but yet enough to be exceedingly annoying and uncomfortable to the patient. I have had two such fistulas following hysterectomy, and neither of them have I yet been able to cure; one, however, now gives fair promise of soon closing. I have, fortunately, had no other fistulæ following my operations.

One patient I know of was a few years ago operated on for some pelvic trouble, and after a few weeks she was sent to her home, with a drainage tube (rubber, I think) in her abdomen. The surgeon lost sight of her, and the tube being neglected, soon became most foul. The patient afterward drifted into one of our large general hospitals and there died.

Another patient was operated on for a pus tube; the second tube and ovary, being apparently healthy, were left *in situ*, but these afterward took on disease and a second operation failed to remove them. A third operation was undertaken, by another surgeon, with what result was never known except by a select few; certain it is that a fistulous track followed, after a severe illness. This woman also finally found her way into one of the general hospitals, and was miserable enough to die, if she did not do so; what finally became of her I do not know.

A third patient had one side of a double tubal trouble removed, and the drainage track never closed. I saw this woman a year or more after the operation, on her death bed. The track was discharging pus freely, and always had done so; before her death, feces were also finding their way through the opening, a slough having evidently come away from the bowel.

A fourth patient, after everything else had been done without success, had a counter opening made into the vagina, by another surgeon into whose hands she had fallen. The operation, unfortunately, opened the bladder, so high up that it was impossible to repair it; she has now a vesico-vaginal fistula in addition to her other troubles, and at last report was in a dying condition.

And so I could go on with case after case, some as bad and some not so bad; but at its best, a fistula is a most miserable complication and too much attention cannot be given to its prevention. If the drainage tube is not responsible for the hernias, it certainly is for a large number of the fistulas; and although I am a firm believer in the great benefits to be derived from free drainage, I fully realize its disadvantages and often wonder if it could not be done away with oftener than it is. The great preventative of the formation of these fistulas is the prevention of abscesses and the necessity of their subsequent discharge; if they do form, it is better to go boldly in and empty them at once, than to wait and have them open by a slow, tedious and uncertain process, which may not be brought to an end before the patient dies; the avoidance of the unnecessary use of the drainage tube, and when it is used, the most careful attention to its cleanliness, and its early withdrawal. I believe a permanent track results oftener from an unnecessarily prolonged use of the tube, than from any other cause.

Fecal fistulas are not so common, and yet enough of them occur from time to time to

be a warning of the danger of their production. When they do occur, they are usually so deeply seated and so bound around by inflammatory products that they cannot be reached, and if they are reached, as a rule, they require one of the most dangerous and difficult operations in the whole range of abdominal surgery. I can recall a number of these accidents: one could not be reached after an extended trial, and the whole incision was closed up in order that the patient might die as quietly as possible; this she did not do, however, but lived in spite of everything and the track afterward closed of its own accord. Another case required the most constant and careful irrigation, after an unsuccessful attempt had been made to reach it, to save the woman's life. And so they go; if an attempt is made to close them, a great risk is taken; if they are let alone and do not close spontaneously, the patient had better be dead. The usual cause, as far as I have been able to observe, is intestinal adhesions to diseased organs. After tearing a loop of gut loose, I have returned it in fear and trembling, lest a piece at the point of adhesion slough out and give me a fecal fistula. The prevention consists in the greatest care in tearing loose each adhesion, and a most careful attention to the after treatment. When fistulæ occur, they are best left alone.

A continuance of pain, or the appearance of a pain not before present, following abdominal section, is so common that every one engaged in this kind of surgery must have noted its frequency. This pain is usually not very severe, but is of a constant nagging character, such a one as so constantly to wear on a woman's nervous system that it soon renders life a misery to herself and makes her a burden to every one around her. At times, however, it assumes a severe character and becomes almost unbearable. I have known of a large number of such cases, some of which required an operation for their relief. In two cases of this kind the only lesion found was an omentum adherent to the abdominal incision, the freeing of which cured the pain. Many others are now going about, suffering as much as they did before the operation. Most of this pain is, I believe due to adhesions formed between the omentum or intestines and raw surfaces left by the operation, and the subsequent dragging on these points. This would seem to be true, as most of the cases which I have known of and which were operated on, and in which the adhesions were released, have been cured, or nearly so. I also think that the adhesions in the original disease often cause most of the suffering; this is especially true in the pelvic cases. From these same adhesions, we have sometimes an obstruction of the bowels, either at once or later, after convalescence, which results in death. I can remember several cases of this kind, which could be explained in no other way and, in fact, some of which were demonstrated to be so by a *post-mortem* examination. The remedy for their formation and all their attendant dangers and discomforts, is to keep the bowels soluble, so that there can be no chance for adhesions to occur. The best way of accomplishing this is by purgatives, and by not using opium. Fortunately the indications for purgatives are so many and so constantly present, that they can almost always be used.

Œdema of the lower extremities, I have seen a number of times. Sometimes it is only temporary but at others it is of long enough duration and severity to be of considerable annoyance and worry to both patient and surgeon. In my own practice this has occurred several times, but has always eventually disappeared.

When every person, about to undergo an abdominal operation, must run the gauntlet of all these complications, as well as many more unmentioned, it becomes a serious matter in deciding for or against an operation. We have here to consider more than the immediate risks to life; we must think, if the patient has his or her present disease removed, will she be any better off, or may she not be the worse for the interference? At any rate, such a state of affairs should be a warning to inexperienced men not to be misled by the brilliant reports seen in the journals, and not to rush thoughtlessly into an operation, expecting to obtain the same perfect results. They should know that, as a rule, only favorable cases are reported, and that men do not like to publish to the world their bad work or misfortunes. Abdominal section is by no means the simple, easy procedure some men would make us believe, and such an operation should never be undertaken except after the most careful consideration of all the risks that must be run, the chances of benefit to the patient, and in the presence of actual demonstrable disease. Until the dark sides of abdominal work are well known to the profession at large, the *furor operandi*, which has been so justly complained of, will continue, and many women will succumb as the results of inexperience.

TREATMENT OF TAPEWORM.

BY TRAILL GREEN, M.D.,
EASTON, PENNSYLVANIA.

The treatment of tapeworm as given in the REPORTER, March 9, is doubtless very effectual when the remedy can be obtained in its active state, but, as stated, "is perhaps a little severe." Pomegranate has been used with very good results, but a decoction of ten ounces is a larger dose than many of our patients would be willing to swallow. You know I am fond of a palatable medicine. The active properties of pomegranate to meet the treatment of tapeworm can be put in less than an ounce of a liquid. I have used the remedy from the time of its introduction, and it has not failed in a single case. I introduced it to the members of our County Medical Society, who have used it with similar success.

Professor Laboulbene, member of the French Academy, who has made the cure of tænia a specialty, but who found it difficult to get good preparations of the medicines which are active in the recent state, wrote: "I wish that some one would discover and separate from the tænicide plants a sure alkaloid, always identical, and that would act with certainty; which is something we cannot obtain from pomegranate bark, or from old koossoo, which is nearly inert." (*Bulletin de Thérapeutique*, 1877.)

M. Tanret obtained the alkaloid from pomegranate bark, and named it pelletierine, in honor of Pelletier, the distinguished French chemist to whom we are indebted for so many valuable discoveries in organic chemistry.

The alkaloid has been used with great success in several of the Hospitals of Paris. Dr. Dujardin-Beaumetz has reported thirty-three cases, of which thirty-two were successfully treated. Professor Laboulbene treated fourteen cases and the tapeworm was expelled in every case. I have never used a tænicide which is so certain to bring away the whole creature—head and body. I very confidently tell a patient: "Soon after taking the medicine you will pass the tapeworm"; and my promise has not failed.

I write this that the members of our profession who have not heard of this remedy may have the pleasure of using that which will be satisfactory to themselves and grateful to their patients. I doubt not they meet with these cases frequently; I find that they are much more common than they were thirty or fifty years ago.

French physicians use with the pelletierine a French purgative, which is not official with us. I find an ounce of Epsom salt to act very well.

LYCOPODIUM DRESSING FOR ULCERS AND WOUNDS.

BY C. P. EDWARDS, M.D.,
GRANITEVILLE, S. C.

During the years 1862, 1863 and 1864 we, as Confederate medical officers, were in want of the usual antiseptic dressings to wounds and ulcers, and were thus taught to experiment with various articles of the materia medica in the hope of finding what would take the place of remedies such as the phenol preparations. Our supply of these accepted antiseptics was cut off by reason of the blockade; our hospitals were crowded with wounded, and our accommodations were tents, churches, and private buildings. The warm and moist climate attracted numerous flies which were nourished and fostered by suppurating wounds of every nature, and with all of our care we would sometimes find a nest of their larvæ in a wound, which would render our patients frantic with unrest.

These were readily routed by applications of oil of turpentine. But the important feature was to guard these wounds with a substance of a protective nature, which embodied the greatest amount of cleanliness. Hence the ointment made from our common elder flowers was adopted, but found objectionable from the unctuous matter used as a vehicle.

Having amused myself by covering water with a coating of lycopodium, and getting the ignorant to introduce their finger through this coating and to withdraw it from the glass in a dry condition, with the lycopodium covering the finger, as with the encasing of a kid glove, I suggested to my esteemed friend, Surgeon W. S. Meire, that we should adopt lycopodium as a dressing to freshly amputated stumps. That night we amputated twelve arms and legs, and having closed the wounds *secundum artem*, viz.: with sutures and adhesive straps, we applied lycopodium freely, and had the satisfaction of seeing eleven out of the twelve wounds heal by first intention.

Since then I have relied upon lycopodium as a dressing to all wounds, and in December, 1888, I was pleased with its application

to a lacerated wound made by a cotton card to the forearm. During January, 1889, I used it twice—once in amputation of the thumb, with laceration of the back of the hand, the second time in a laceration of the palmar surface. Both wounds healed by first intention.

Let each surgeon now ask himself: What is lycopodium? Sulphur is death to insects. Lycopodium is a vegetable sulphur. In twenty-six years' use of it, I have never had any bad results in treating surgical wounds with it. I would therefore respectfully ask a trial of it by the other surgeons of our country, feeling assured that they will not be disappointed in the results obtained.

Society Reports.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Thursday, March 7, 1889.

The President, Theophilus Parvin, M.D., in the Chair.

Dr. J. M. Baldy read a paper on

Complications Following Abdominal Section.[1]

Dr. William Goodell, in opening the discussion, said he wholly agreed with the writer of the paper in regard to the stubborn nature of these fistulæ and to the impossibility of avoiding them. He had now three cases of fistula. One followed the removal of an intraligamentary cyst, in which he had reopened the wound for bleeding. The patient recovered, but a fecal fistula had made its appearance about the fifth day after operation and had never closed. He had to peel off the tumor from the rectum. It was now a year and a half since the operation, and the patient was in the hands of a competent surgeon in the country. The only annoyance to her is an escape of gas from the wound. The second case followed the prolonged use of the drainage tube, after abdominal section for pelvic abscess. He had not had charge of the after treatment, but the patient was in the hands of a skilful surgeon. It may be needful yet to make a counter-opening in the vagina. The third case was one of recurrent intraligamentary cyst. The fistula resulted from a previous operation, in which the surgeon used the clamp, many years ago. Dr. Goodell operated last November, and removed a recurrent cyst lying in a very large abscess cavity. A drainage tube was then used, which he still kept in, because he could not get the fistula to heal from the bottom. He had just made an application of iodine to the track, and told the husband to repeat it daily for a time. He has had cases of fistula when the drainage tube was not used, but they were due to non-encapsulation of the pedicle ligatures. In one while using the syringe the ligature was washed out. This gave him the cue, so in the others he fished the ligature out by means of a small hook on the end of a fine wire. On the other hand, in the case of an ovarian abscess, he had kept drainage up for several months, and yet the track closed. It is his intention in a third case to pass nitric acid to the bottom of the fistula, and see what can be accomplished in this way. In this case the patient menstruates through the track.

Dr. Goodell thought that if operators would wait some time after they have operated, before reporting their cases, they would find a number of hernias. He takes a good deal of pains to avoid this accident, and he closes the abdominal wound in an analogous way to that described by Dr. Price. The tendon when retracted he brings forward, as much as possible, with forceps, so as to bring it in contact with its fellow. He has had cases in spite of every care. In the official report of Imlach's cases, although these were all cases of oöphorectomy, needing a very short incision, the percentage of hernias was fifteen. Dr. Goodell keeps his patients in bed for two weeks, before allowing them to sit up. In two cases in which he removed the ovaries, in fibroid tumors, he has had the incision rupture, from too early taking out of the stitches. In these cases he sometimes leaves them in for two weeks. One patient went home nineteen days after operation, in spite of orders, and the train becoming derailed, the jarring forced the cutaneous part of the wound open. Stitches had to be put in.

Dr. M. Price does not think with Dr. Baldy that abdominal surgery has anything to regret in these cases. He admits that much of the dirt and filth and many of the accidents which follow these terrible operations are actually due to the surgeon. He does not wonder at there being fistulous tracks, for the reason that in many of these

[1] See Reporter, page 420.

cases the adhesions to the bowel are of such strength that their separation often removes everything down to the mucous coat. He has seen as many as six or seven sutures applied to such a case. Fistula is a repetition of the old abscess, which finds its way to the surface through the drainage track. All of the disease has not been removed. In many cases the fistula saves the woman's life and gives the surgeon a path through which to perfect his otherwise imperfect work. Fistula is a proof that the case has not been properly cared for. He does not believe that thirty per cent., or even five per cent., represents the number of hernias. He has only seen two cases follow. Their closure is unattended with danger. If due care and cleanliness are observed, fistulæ will not occur.

Dr. J. Price was a little surprised that one so deeply interested as Dr. Baldy, in this subject of abdominal surgery, should stimulate criticism of our present position. Dr. Baldy speaks of hernia. The position of the incision, the condition of the abdominal walls, and the manner of introducing the sutures are of great importance. Death has followed tight sutures and he is satisfied that hernias often follow them. He always draws his sutures lightly. If three or four are used to the inch, tied lightly, with perfect coaptation, the results will, as a rule, be perfect. In introducing sutures he takes in half as much skin as fascia, and twice as much fascia as peritoneum. This gives better apposition to the centre of the wound. He has not had a suture-track abscess for more than a month, nor has there been any mischief about the tube. Nursing is of the greatest importance. The old nurses are meddlesome and dangerous, and he is glad to see them replaced by younger women. The tube can be dispensed with very often if the irrigation is thorough. Most surgeons are in too much of a hurry to get their patients up. Early rising is dangerous, and he has known surgeons to brag of getting their patients home in ten days.

In fistulous tracks, through which menstruation occurs, the only thing to do is to tie the tube and release it from the abdominal incision. A drainage tube resting against the torn bowel surfaces favors the occurrence of a fistula. A man who gets scared at a fistula or ventral hernia is not prepared to do good work; his work begins in doubt and ends in disaster. The operation for curing a ventral hernia is not dangerous.

We cannot ignore the importance of precision in diagnosis. We must try to decide as to the probable nature of the lesion. Dr. Baldy calls attention to one point, that is, the necessity of recognizing something definite on which to operate. Savage and others are satisfied to operate for subjective symptoms only. This is not right. The other day Dr. Price refused to operate on a patient who had multiple abscesses in the lungs. Two weeks before he had gone to the house prepared to operate, but the family had refused. The time will come when operators will be most arbitrary in these cases. We shall have the right to say that if the general practitioner waits until the eleventh hour we will not step in. Last summer a patient refused operation, to-day she sent for Dr. Price and requested it.

Peritonitis is often due to an imperfect toilet. It is often of limited extent or localized, leaving adhesions to portions of the viscera. This is a common source of pain and discomfort. The only good remedy is to do the work over and release the adhesions. This past summer he had either done himself, or assisted others to do, eight of these operations over, and they had been the most difficult and trying of his whole experience. He wished to call attention to one case on which he had operated three times. Dr. Baldy saw the work. When he first saw the patient pus was escaping from the umbilicus. He opened the abdomen, but failed to remove anything. Drainage was followed by a good recovery, but the wounds did not close. A year later he re-operated, but a fistulous track was left. Again a year later he used a catheter made of coils of wire. He passed this along around the ileo-pectineal line, toward the region of the kidney. He dissected along the pelvic bones and irrigated through the catheter. Last week, the patient was delivered of a fine baby. In this case he could find the ovaries, and there was no lesion of them or of the tubes. This is the only case of pelvic abscess without tubal disease he has ever seen, in a long and rich experience.

He wished to speak of two of the cases referred to by Dr. Baldy in his paper. One case he had operated on early in his experience, and had removed only one side of a specific tubal trouble. This he would never do again. The patient went into other hands, and he did not care to refer to the surgery which followed. Another case of which he had personal knowledge, was a case of imperfect surgery. This was a large pus sac, which could have been removed

but was drained. The woman died of psoas abscess. Skene has called attention in his book to the fact that pelvic abscess frequently causes psoas abscess. The incomplete removal of diseased tubes should be rectified. If an inch of tube is left it will most likely do mischief. He has curetted into the cavity of the uterus, removing a cone-shaped piece. The tubes should be tied hard on to the uterus, and the ovaries should be tied at a good surgical neck, and the results will be about perfect.

Dr. Montgomery said: We have become so enthusiastic in the field in which we are working as perhaps to overlook the dangers and difficulties, and in our desire to defend and possibly to push forward our own work, we sometimes fail to report our disasters. I think that Dr. Baldy has done us a kindness in dwelling on some of the disasters that may occur in abdominal operations. I am rather surprised to find that hernia is such a frequent lesion, in his experience. I have not found it so. The method of closing the wound suggested by Dr. Price, is the one that I have largely used, and unless Dr. Baldy has come across some case of which I do not know, I have never had a hernia in my experience. Fistulas with a constant discharge are exceedingly depressing and distressing. I have thought that drainage *per vaginam* might be preferable, where this accident is liable to occur. In such a case if fistula did follow, it would not be so bad as if it were in the abdomen. I operated last fall on a case in which half a gallon of broken-down blood was removed from a sac. The sac was drained, but death occurred in a few days. The *post-mortem* showed an abscess below the sac, which would have been opened if vaginal drainage had been performed. The after-treatment is exceedingly important in many cases. These results are no doubt due to the fact that there still remains some diseased tissue about the ligament or uterus. Where the tubal disease is gonorrhœal, it is very hard to tie close enough to the uterus to remove all the pyogenic membrane. Even when we do the inflammatory condition is still present in the uterus. The tendency of the extension of such inflammation to the pelvic tissues is in many cases the cause of after trouble.

Dr. Hirst said that in three cases which he had lately to deal with, fistulæ directly followed laparotomy. One woman died a year after the operation in consequence of this complication. In one case of great interest a mass of ligature was fished up, but the fistula still remains. After waiting sometime he opened the vault of the vagina, behind the uterus, on the point of a sound passed into the fistula from above. He did not think he could have opened the bladder, but a vesical fistula must have already existed, for when he cut through the vault of the vagina, urine gushed out. A drainage tube was put through the whole track, but now four months have passed and the woman is dying. He would hardly think the use of nitric acid free from danger, used as recommended by Dr. Goodell.

Dr. Baldy said: I did not bring these cases forward as an objection to abdominal surgery, nor would they, nor many more, stay my hand if I found a case which required operation. My desire was to call direct attention to such accidents as these and to stimulate our efforts to prevent their frequency. Nor is this by any means a complete list of all the cases on which I could put my hands. I could add dozens to the ones I have named. These cases have occurred in the hands of prominent men, men who profess to be teachers and who number their cases by the twenties, fifties and hundreds. If we see such accidents in the hands of such men, we shall have more serious results in the hands of those less expert. Many cases of fistula can be avoided by care in the use of the drainage tube. Few surgeons understand how to take care of a tube properly. I cannot agree with Dr. Price that fistulas always follow old fistulous tracks, and are caused by diseased tissue left behind. In the majority of cases that I have seen the diseased tissue has all been removed and the track occurs through what was formerly clean, healthy tissue. I think that one common cause of hernia is the use of hæmostatic forceps. These bruise the tissues and if allowed to remain on too long cannot help irreparably damaging the vitality of the parts included between the blades. The less we use the forceps the better union we will get. It is a rare occurrence that I have to use more than one or two pairs, sometimes three. These are always removed in a few moments—in fact, as soon as I open the peritoneal cavity. They are no longer needed and often, if we are working through a small incision, are in the way. The fewer foreign bodies in and about the abdomen and abdominal wound, the better for the patient and the easier for the operator. Cleanliness in all its details cannot be too strongly insisted upon.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, March 21, 1889.

The President, ALFRED L. LOOMIS, M.D., in the Chair.

The Place of Electricity in Therapeutics.

The discussion on this subject was opened by DR. M. ALLEN STARR, the title of whose paper was,

The Physics and Physiological Actions of Electricity.

By electricity a new molecular state is produced in the body, but nothing is added to or subtracted from the body. Between the two poles this molecular change is more intense than elsewhere. He thought the term "current" responsible to a certain extent for the erroneous opinion prevailing regarding the action of electricity in therapeutics. The forms of electricity are frictional or static, voltaic or galvanic, and induced electricity or Faradism. He thought too much credence had been given to the therapeutic action of static electricity, for its effect is confined to the surface of the body, unless it acts reflexly; it is only mildly stimulating, and serves this purpose no better than massage or other mechanically acting stimulants. Besides, this object can be as well obtained by means of galvanism, which can also be used for permanently charging the body and in producing catalytic, cataphoric, and electrotonic effects. For disintegrating the bodily tissues galvanism has but a limited application in therapeutics. It is used for the removal of hairs, but gives place to other surgical procedures in the removal of tumors, etc. As to its use for stimulating nutrition, as in paresis of certain forms, he knew of but one scientific observation, that of Dr. Thatcher, in a case of paresis of the upper extremities, in which galvanism hastened recovery, while Faradism produced no such effect, and massage did actual harm. He has never seen a case of organic disease of the brain or spinal cord which he could consider cured by the application of electricity. Some cases improved under the treatment for a time, then grew worse, while others did not improve at all.

Regarding the power of reaching the deeper tissues, it is to be noted that the body is homogeneous, and that the power of conducting electricity in different tissues is variable. But little of the current reaches, for instance, the brain or cord, in proportion to the amount applied to the surface. It is not impossible that favorable nutritive effects are produced by the increased circulation, and more rapid chemical changes brought about by the agent, as in lead palsy; yet he has not been able to convince himself of definite benefit attributable to this remedy alone.

There is no doubt of the power of electricity to promote osmosis, and this quality has been made use of in introducing drugs to allay pain.

Dr. Starr's conclusions were as follows: 1. Static electricity offers nothing more than the interrupted galvanic current, and fails to furnish those effects which are most desirable in the treatment of disease. 2. The constant galvanic current can produce chemical changes which aid nutrition or destroy tissue according to the strength employed. 3. The constant galvanic current can transfer medicines within the body from without. 4. The interrupted galvanic or Faradic current can excite various organs to functional activity. 5. It is questionable whether the pathological state causing organic diseases can be in any way influenced by electricity. 6. If functional diseases are benefited it is in an uncertain manner. The agent, therefore, is used empirically, and the physiological indications for it are as yet uncertain. As a therapeutic agent its use is somewhat limited, and a careful weighing in the balance is required to establish its sphere.

He concluded by saying that after the constant use of electricity during the past ten years he must acknowledge to disappointment in the results obtained.

DR. LANDON CARTER GRAY read a paper on

The Effects of Electricity in Central Nervous Diseases.

He first made some remarks suggested by Dr. Starr's paper, and said that he would undertake as positively to obtain certain therapeutic effects from electricity in certain neuralgias and neurasthenic cases as he would from opium in other diseases. He did not claim, however, to cure the organic disease, and no more could be said of any drug in the Pharmacopœia. A great deal depends upon the way in which electricity is used. Electricity is useful in the functional insanities only in the period of convalescence. It is not considered in chronic and incurable forms. It is also beneficial in certain of the gross diseases of the brain, as in the early stage of cerebral syphilis, before hemiplegia

has supervened. Meningitis of traumatic origin, producing hemiplegia, if slight, may be benefited by electricity, and if hemiplegia of vascular origin is not followed by contracture it can also usually be thus benefited. *Tic douloureux* is uncertain in its response to electricity.

The two currents which will answer every purpose of the physician are the galvanic and Faradic. The administration of electricity in diseases of the brain consists of cerebral galvanization and peripheral Faradization. Regarding the choice of poles, he could lay down no other rule than this: where one pole does not agree, try the other; and if that does not agree, stop using electricity. The question of the ascending and descending current has of late years been merged into the question of poles; although he thinks there is a difference, he knows no indication for one more than for the other. He said this in spite of the indubitable differences chemically, physiologically, and pathologically between the negative and the positive pole.

Dr. W. R. Birdsall discussed

The Effect of Electricity in Spinal Cord Diseases.

He thought much of the disappointment of some persons in the employment of electricity is that they have anticipated too much of it. He agrees with Dr. Starr, that he has never seen it cure a case of organic disease of the spinal cord, but then he has never seen any other single remedy do this. Electricity, however, is beneficial in relieving certain symptoms attending these affections, as pain, anæsthesia, spasm, paresis, trophic changes. He regards its action as essentially stimulant, an excitor of living tissues.

Dr. A. D. Rockwell read a paper on

Effects of Electricity in Peripheral Nerve Lesions.

He has found the agent beneficial in several of the neuralgias, especially facial paralysis, in which the form of current to be used depends upon whether the intramuscular nerves have at the outset become completely paralyzed for the time being. If so, Faradic electricity, which exerts its influence chiefly upon them, would produce no response, while galvanic electricity would produce contraction because it influences principally the muscle fibre which is still intact. Electricity is useful in diphtheritic paralysis.

Dr. E. D. Fisher read a paper on

The Effects of Electricity in Functional Nerve Affections.

In the course of his remarks he said he would not discard static electricity quite so positively as it would seem Dr. Starr would do. He thought it had its uses in neurasthenic cases and in those functional affections characterized by errors in nutrition.

Dr. Putnam Jacobi summed up the statistics of uterine fibromata treated by electricity. They were not very extensive nor very definite. Those who had reported their experience with it had often seen relief from symptoms, and some diminution in the size of the tumor.

Dr. George W. Jacoby took much the same view of electricity as a therapeutic agent as Dr. Starr had done. The agent being used empirically, had been resorted to in every disease and symptom imaginable. Very frequently benefit was reported in cases which it is likely would have recovered without the electricity.

Dr. Leopold Putzell also thought those who attributed good results to electricity often overlooked the natural course of the disease. In facial paralysis, and diphtheritic paralysis, which had been referred to by Dr. Rockwell, this statement is true. The Faradic current applied with the brush over painful points in neuralgia often has a rapid effect. In one case varicose veins of the leg of twenty years' duration practically disappeared under Faradism.

Dr. J. H. Girdner had been experimenting to determine the electrical state of the human body in health and disease. Putting one pole in the mouth and the other in the rectum, a considerable difference in the electrical state was found under varying conditions. The variations were especially great between health and disease. This is not to be attributed to the fluid at the pole.

Dr. Peterson said he had lately been employing electricity in introducing a mixture of cocaine and aconite under the skin and at painful neuralgic points. He has thus been able to quiet pain for from five to eleven hours.

Dr. William H. Thompson distinguished between the influence of galvanic and Faradic electricity, and said that he had obtained much benefit from the latter in stimulating the arterial circulation of parts and thus overcoming paresis, and causing absorption of exudates in subacute affections, as articular rheumatism, pleurisy with effusion, etc.

Dr. Andrew H. Smith has found quicker and more positive benefit from static electricity than from any other form in stiffness and soreness of parts due to exposure to cold, as in stiffness of the hand and wrist of stage drivers, etc. He thought the electrical variations observed by Dr. Girdner were to be attributed to substances accidentally present in the body.

Dr. Starr, in closing the discussion, said, respecting the action of Faradism being directed more especially to the intramuscular nerves and galvanism to the muscular fibres, that there is no truth in this statement. The reason why Faradism does not produce a response is that the interruptions are too rapid. Make them slowly and the muscle will respond to it as well as to galvanism. He said the discussion had confirmed him in his view that electricity is of limited value in therapeutics.

Reports of Clinics.

PHILADELPHIA HOSPITAL.

CLINIC UPON OBSTETRICS, AND DISEASES OF CHILDREN—DR. PARVIN.

Death of an Infant from Hemorrhage from the Mouth.

Dr. Parvin first spoke of the death of an infant from hemorrhage from the mouth, a few hours after birth, and said: A most unusual case recently occurred in the Maternity. A woman was in labor, the presentation being pelvic; after the delivery of the body, and after the face had rotated posteriorly, the resident physician, anxious to keep the head well flexed and also thus facilitate delivery by traction, pressed upon the lower jaw with one or two fingers partly introduced into the mouth; the child was delivered living, but a short time after birth the nurse observed blood oozing from the mouth. Upon examination there was found blood coming from just beneath the tongue on one side. Various means to arrest the flow were tried, but they were unsuccessful, and the child died. It has been supposed that this child was a "bleeder," that is, suffered from hemophilia. The bleeding, whether traumatic or spontaneous in such a subject, is rebellious to remedies; such was the fact in this case, and so, reversing the familiar statement that the cure proves the disease, we might say the failure to cure may also prove the disease.

The point, however, to which I desire to call your special attention is as to the management of head-last labors with reference to assisting flexion and hastening delivery, when posterior rotation of the face has occurred after the expulsion of the body. The method most generally recommended is that known by the compound name Smellie-Veit. Two fingers of one hand are introduced into the mouth, care being taken to press only upon the alveolar processes of the lower jaw; at the same time two fingers of the other hand are passed over the nape of the neck; traction is now made, chiefly with the fingers pressing upon the lower jaw. But may we not produce safer and equally effectual pressure with two fingers upon the superior maxillary, while two fingers of the other hand press up the occiput, and thus secure the prompt expulsion of the mental end of the occipito-mental diameter?

Of course, a prompt delivery is imperatively necessary when this stage of labor is reached, for the child is liable to perish from asphyxia, the chief source of such asphyxia being pressure upon the cord, assisted by partial detachment or very great compression of the placenta when the uterus is so nearly completely emptied, provided its normal retraction has occurred. I cannot but think that pelvic deliveries are more liable to be attended by intra-cranial injuries, which, though not always mortal, may have a very injurious effect upon the child's condition. Cruveilhier has stated that of the children perishing in labor, one-third die from cerebral hemorrhage. In recently looking over some statistics of convulsions or of paralyses following labor, and of defective mental development, I was struck with the relatively greater number of these unfortunates that had been born by a pelvic presentation, or after podalic version had been performed. If this be true the explanation probably is found in the necessarily rapid passing of the head, before time can be given for its molding, through the bony pelvis, and hence injurious compression made with consequent intra-cranial hemorrhage. The head must be delivered quickly, or the child dies: but this delivery may be secured by the sacrifice of the child's health—it comes into the world possibly to live only a few days, months or years, but at best living an imperfect, incomplete life.

Intra-Cranial Hemorrhage.

Seventy-two hours after its birth an infant in the Maternity was attacked with convul-

sions, and in twelve hours died. The autopsy revealed a hemorrhagic clot upon the right side under the dura mater. There was no external injury, and the labor had ended spontaneously and was not long. I mention this case to show you an example of intra-cranial hemorrhage caused by natural labor. The rule is that, if the effusion of blood be considerable, death takes place within twenty-four hours. The fact that this child lived so long before symptoms occurred and then for twelve hours afterward, shows that the rule must not be regarded as absolute. Where a diagnosis of hemorrhagic effusion has been made, it has been proposed to aspirate; but it seems to me that this would be very uncertain treatment, for it could not remove a clot, nor could it furnish any guarantee against a fresh effusion.

Induction of Premature Labor in Contraction of the Pelvic Inlet.

The measurements that have been previously taken, and which have now been again taken before you in order to give you an illustration of pelvimetry, prove that this woman, who is in her eighth month of pregnancy, has a pelvis of which the true conjugate is somewhat under four inches. You know that in the mechanism of labor in the simple flat pelvis, the fœtal head passes through the inlet with its biparietal diameter in relation with the true conjugate. When once the head has made this passage, cleared this strait, there is no more trouble in the labor. Now although in this woman, supposing the bi-parietal of the child's head at term to be three inches and a half, the true conjugate exceeds it by a small fraction of an inch; and although the former diameter may be reduced one centimeter, or about two-fifths of an inch, and therefore labor at nine months would probably be difficult, yet it is also probable that the woman could deliver herself, and it is possible her child might be born living, and without any intra-cranial injury such as has been referred to. It would nevertheless be safer to induce premature labor early in the ninth month. Bearing in mind that the increase of the biparietal diameter in the latter months of pregnancy is one centimeter a month, you determine, after having ascertained the degree of pelvic contraction, the time for the induction of premature labor, endeavoring to delay this as long as is safe for mother and child, so that the latter may have the best chance of living after delivery. Many a child born prematurely perishes, but I confess I was somewhat startled by reading in Winckel's recent work upon obstetrics that the fœtal mortality after the induction of premature labor is 66.6 per cent.

The question as to the means of inducing premature labor may be asked. That method which most obstetricians employ is the one known as Krause's, that is, by the introduction of an elastic bougie between the ovum and the uterine wall. Quite recently I was reading in a French journal the history of a case in which such introduction, though attempted by an able hand, was impossible; the difficulty arose from a very marked anteflexion of the uterus: the operator then succeeded in bringing on labor by the use of tents.

Of course all antiseptic precautions must be used in this operation; the bougie must be clean, and dipped in an antiseptic solution—for example, in a solution consisting of 1 part of corrosive sublimate to 1000 of water; the vagina must be thoroughly cleansed with an antiseptic solution. The operator's hand, after careful and complete washing, must also be put in a similar fluid. Then the bougie is carefully passed into the uterus, made to feel its way, insinuate itself between the ovum and the uterine wall, always moving it in the direction of the least resistance, until it is quite within the uterus. Labor in the majority of cases begins within twenty-four hours; but in some it may be delayed for days. What is to be done in the latter case? Repeat the application of the bougie, only at each new introduction give the instrument a different direction from any that it previously had.

COLLEGE OF PHYSICIANS AND SURGEONS—VANDERBILT CLINIC.

CLINIC FOR GENITO-URINARY DISEASES—PROF. OTIS.

Gonorrhœa.

In the previous lecture Dr. Otis discussed acute gonorrhœa, but he said it would be improper to dismiss the subject without reference to those long-standing cases of acute gonorrhœa in which the inflammation is not confined, as usual, to the anterior part of the urethra, but extends to the membranous portion, and beyond; sometimes involving the bladder, ureters, and even the kidneys. The causes which tend to produce this condition are excessive exercise, bad living, alcoholic

indulgence and, most decidedly, sexual indulgence, both in act and thought.

The first symptom that will call attention to the disease is frequent urination, which is a sign usually that the neck of the bladder is involved. For relief of this, rest is most important, together with suppositories of opium or enemata of hot water. It is most essential that the sound and catheter be not used during this stage. Even should there be retention of urine it is advisable first to employ other means of relief than the catheter, such as hot baths, hot enemata, and 5 to 10 drop doses of the muriated tincture of iron, every hour, in the hope of thus relieving the retention.

In cases of involvement of the deeper urethra there is danger when using instruments of pushing the contagion further on. But when the bladder is once involved there is no longer necessity for avoiding the use of catheters.

The treatment of the condition under consideration is by the injection of a few drops of a solution of nitrate of silver, 3 to 5 grains to the ounce, directly upon the membranous urethra. It is also one of the most reliable means of curing a beginning cystitis.

Chronic gonorrhœa is due to the fact that on the diseased spots the epithelium is not replaced because of the plastic material beneath. When endoscopy first came into employment it was supposed that its value would be very great, that these spots could then be exactly located and applications made directly upon them. But even after this treatment and after the patient had been discharged apparently cured, it was found that very frequently he came back, perhaps months afterward, complaining of a return of his discharge. In reality a stricture is at the bottom of most of these cases, and it is only when this is removed that we can expect a permanent good from the applications. Often the cure of the stricture will stop the discharge.

Case I.—The patient was a man 30 years old, who presented himself with chronic gonorrhœa. He has several strictures which will not now be located. By the endoscope we see evidences of these as well as patches of inflammation. The treatment now recommended in such a case as this would be the irrigation of the urethra after the following method. A syringe, holding several ounces of a medicated solution, is attached to a catheter and the catheter is passed down to the membranous urethra, not into the bladder. The syringe is slowly emptied through the catheter, the fluid passing along the deep urethra into the bladder. The apparatus is withdrawn and the patient voids the injection, thus medicating the entire canal. The following solutions are recommended:

No. 1 Acidi Carbolici,
Zinci Sulphatis,
Alumenis . . . . . āā 1 part
Aquæ . . . . . 1500 parts
at first; then 1000; then 500 parts

No. 2 Potass. Permanganat. . . . 1 part
Aquæ . . . . . 1000 parts

No. 3 Argenti Nitrat. . . . . 1 part
Aquæ Destil. . . . . 1000 parts

To this method there is only one objection, namely, it may set up a prostatitis; this is clearly due to the impact of the fluid against the prostatic urethra. The same complication sometimes occurs after the passage of a sound. It is an objectionable occurrence as it is liable to be persistent, not unfrequently lasting a year or more; and being evidently due to the measures used by the physician he is pretty sure to be credited with it. So that although Prof. Otis has had most excellent results, especially from injection No. 1, employed in this manner in chronic urethritis, and also in cystitis, his advice would be not to use this procedure, but rather the ordinary syringe employed in the usual way. He decidedly advises against the use of a sound in these cases, previous to the large injection, for the purpose of ironing out the mucous membrane.

After the employment of these or similar injections, in many instances, the discharge continues. Then the endoscope may be used. But after all, though this instrument is of undoubted utility it is not a necessity. We can locate the diseased and tender areas as well with a bulbous sound, and in this manner as accurately apply our nitrate of silver as through the endoscope.

Stone in the Bladder.

Case II.—The patient was a man, 55 years old. For two years he has had trouble in urinating, micturition being frequent and but little urine passing at a time. He has had pain at the end of the penis. The urine has never stopped suddenly while being voided. This last is a valuable symptom, but it is well to remember that this and all symptoms may be frequently absent. Dr. Otis recalls a case in which a very large stone existed for many years without any symptom of bladder trouble.

In examining this man he first elevated the hips so that the stone fell to the upper part of the bladder. Passing in the

sound he found a calculus, and applying the Billroth audiphone the click of the sound against the stone was heard 30 feet away. It was a large stone. If it had been found small, by measurement, it might have been crushed before the class, but he does not like to operate in such a case as this unless he is able to put the patient at once to bed. In this man there is some narrowing of the urethral canal as well as considerable spasm. The physician should always attend first to the determination of the condition of the urethra. Then before operating, he should make due preparation, by making the urethra large enough to facilitate the main operation.

The difficulties in litholapaxy are not from injuries to the bladder, but from irritation to the urethra. This point Dr. Otis was the first to make in 1881, and he believes it now fully proved by *post-mortem* evidence.

PERISCOPE.

To Avoid Corrosive Sublimate Poisoning.

In a communication to the *Amer. Journal of Obstetrics*, Feb., 1889, on the Puerperal Uterus, Drs. F. L. and John R. Haynes give the following advice:

1. Where intra-uterine irrigation is used in the absence of sepsis, use no sublimate, but plain hot water, or salt and water.

2. If the urine is albuminous and scanty, use no mercury.

3. If the urine is slightly albuminous and copious, or if the patient is profoundly anemic, do not use more than a pint of a solution of 1 : 8,000.

4. Always use tartaric acid and sublimate tablets or powders; dissolve thoroughly in a small quantity of water and mix carefully with a definite quantity of hot water in a pitcher, from which pour into the irrigator.

5. Always use a fountain syringe, and for the uterus a double tube, so as to insure the return of the solution. If for any reason the fluid fails to run out as fast as it flows in (if not through the reflux tube, by way of the channels at its sides), shut off the flow. The irrigator should not be raised more than three feet.

6. Precede by copious irrigation with hot water to wash out blood, etc., which may form with sublimate adhesive albuminous compounds, which may in time be absorbed. Follow by a quart or two of hot water to insure the evacuation of all the sublimate solution.

7. For the uterus, use a solution not stronger than 1 : 8,000 and not more than a quart, once daily.

8. For the vagina, use a solution not stronger than 1 : 4,000 and not more than a quart, twice daily.

Irrigation used in the above way is, they believe, a practice almost devoid of danger. They have made more than one hundred and seventy-five irrigations with the double tube and fountain syringe, with no untoward results, except in two cases an unimportant rise of temperature, and in one a severe but harmless chill; and even these slight accidents they are certain might have been avoided by greater care. Nevertheless they assert that irrigation of the puerperal uterus will always be a procedure requiring great care and judgment and some skill. They agree with Credé and Fehling, that both vaginal and uterine irrigations are attended with undoubted dangers, and should never be employed in the puerperal state unless to meet definite indications.

Chloroform Administration.

At the distribution of the prizes to the students of the Hyderabad Medical School, by their Royal Highnesses the Duke and Duchess of Connaught, on January 25, Surgeon-Major Lawrie, M.D., Principal of the Medical School, in a short address, referred to the commission appointed last year by the Nizam's Government, to make experiments with reference to the effects of chloroform. Dr. Lawrie said the experiments which had been carried out by the commission, consisting of Dr. Hehir, Mr. Kelly and Mr. Chamarette, were, in his opinion, the most important that had ever been made, and had conclusively decided a question which had been in dispute ever since chloroform was first introduced. There is no doubt, he said, that the anæsthesia produced by chloroform is best measured by its effect on the breathing, and that when the administration is pushed beyond a safe point, the breathing becomes embarrassed and then stops. The question in dispute is whether chloroform ever affects the heart directly or not; and this is important in its bearing on the way in which the administration of the anæsthetic should be conducted.

The following was the work performed by the commission, as described by Dr. Lawrie. They killed with chloroform 128 full-grown pariah dogs, averaging over twenty pounds weight each. This does not represent a tithe of the experiments they actually performed, which really amounted to several

hundreds, as they varied the dose and the method of administering the chloroform in every possible way, and tested the value of artificial respiration in nearly every case by reviving the dogs over and over again after the breathing had stopped, and before the heart ceased beating. What they found was, that no matter in what way it was given, in no case did the heart become dangerously affected by chloroform until after the breathing had stopped. "This," adds Dr. Lawrie, "tallies exactly with my own experience. I have given chloroform as often, or oftener, than any man living, and have never had a fatal case; and I can state positively that in the 40,000 or 50,000 administrations I have superintended I have never seen the heart injuriously or dangerously affected by it. I take no credit to myself in this matter. I have simply carried out in India the principles Simpson and Syme practised and taught in Edinburgh." In the hospitals attached to their school, chloroform was invariably given with absolute, or with almost guaranteed safety, by students, and they were never allowed to examine the heart beforehand, or feel the pulse during its administration. In other places, and in London itself, deaths from chloroform constantly occur, but provided the administrator could swear he examined the heart and felt the pulse, they were always supposed to be accidental. Dr. Lawrie has no doubt deaths will go on occurring until the London schools, which of course influence the whole world, either entirely change their principles and ignore the heart in chloroform administration, or else confine themselves exclusively to the use of an anæsthetic like ether, which, with all its disadvantages, they know how to manage.—*British Med. Journal*, Feb. 23, 1889.

How to Preserve the Hands.

Dr. George Meyer, of Berlin, in a paper published in the *Berliner klin. Wochenschrift*, Jan. 14, 1889, says that in using the different methods of disinfection for the hands, which are at present considered necessary, the skin is always more or less affected. Reddening, eczema, and cracks of the skin are often the results of repeated washings and scrubbings with antiseptic materials, so that at times entire abstinence from the use of disinfecting fluids seems necessary. Fluid antiseptics contribute especially to roughening the skin of the hands, which results in the skin becoming cracked when the hands are subsequently exposed to the cold air and are not sufficiently dry.

There have been several methods, Dr. Meyer says, which have been proposed to keep the skin of the hands, especially physicians' hands, soft and pliable. He then speaks of a method recommended to him by Professor Liebreich, which is very easy to carry out. It has been of more use to him than all other formulas during the years that he suffered with red hands. It has nothing to do with the disinfection of the hands, but merely serves to keep their skin in a normal condition. His own hands, which for years were red and tender, have since its use become nearly normal in color. Moreover, he says he can use it with all disinfectants, without having to fear any further effects on the hands, since its use renders the skin smooth and soft.

After thoroughly washing the hands with a soap that makes a lather easily, they are well wiped and thoroughly dried; then the hands, especially the one most exposed to infection in the daily intercourse of life, is rubbed with a little lanolin, and any excess removed with a handkerchief. Other substances may be added to the lanolin, according to preference; Dr. Meyer uses the following:

℞ Lanolin Puriss. . . . . 98 parts.
Extract. Vanill. . . . . 2 parts.
Olei Rosæ . . . . . gtt. j.

This, he says, is a salve for the skin which he has always found satisfactory. It has been shown that a smoother salve can also be made by the following formula:

℞ Lanolin . . . . . 79 parts.
Liquid Paraffin . . . . . 19 parts.
Extract. Vanillæ . . . . . 2 parts.
Olei Rosæ . . . . . gtt. j.
M. et ft. terendo unguent.

For applying away from home the lanolin may be carried in small metal collapsible tubes. The ointment is to be reapplied after every washing, and each time in such a way that the lanolin will be thoroughly rubbed into the skin. This is especially recommended during the winter. In speaking of the favorable effect of lanolin, he mentions its power of mixing with water, by virtue of which, after washing the hands, any water remaining on the skin from imperfect wiping is absorbed by the lanolin, and the hands prepared for the cold with the least possible grease. By these two latter qualities the hands are prevented from cracking and reddening.

In practice he has used the method with good result for rubbing on the face, as in actors, whose skin had suffered from the use of paint.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.00
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

PALPATION OF THE KIDNEYS.

It is a curious fact that, within the last few weeks and almost simultaneously, two distinguished clinicians of Europe have published important communications in regard to palpation of the kidneys for diagnostic purposes. Both Guyon, in Paris, and Israel, in Berlin have recently cited their observations and experiences to show that the kidneys are not so inaccessible to touch as is commonly supposed. The former has described his methods of investigation in a lecture at the Hôpital Necker, reported in the *Gazette Hebdomadaire*, Feb. 8, 1889, with great clearness and instructiveness, while Israel has published a very valuable article on the subject, in the *Berliner klinische Wochenschrift*, February 18, 1889.

Progress in treating diseased kidneys is now needed, as Israel states, more in the direction of finer methods of diagnosis than in that of the technique of surgical operations. The kidneys are situated upon the posterior wall of the abdominal cavity, upon the lowest dorsal and the three upper lumbar vertebræ. Their upper half is covered by the wall of the thorax, their lower half only by soft parts. Their diameter from hilus to convexity is directed obliquely, with the hilus presenting in front and toward the middle line. Their long axis is also obliquely placed, being nearer the spinal column above than it is below. The right kidney is placed at a slightly higher level than the left. If a line be drawn from the middle of Poupart's ligament, parallel to the linea alba, and a perpendicular be let fall from it two fingers' breadth below the point where it meets the lower border of the ribs, the perpendicular will meet the normal kidney. As Israel says, a correct understanding of these simple anatomical facts is of the greatest moment in examining the kidneys.

To utilize them certain favoring conditions are essential. The abdominal fat must not be too extensive, and the tension of the parietes must not be too great. To facilitate an examination, the bowels must always be emptied, and chloroform may be administered to relax the muscles of the abdomen, although anæsthesia interferes with voluntary deep inspiration, which is often of great assistance. Emptying the bowels not only diminishes their tension, but also removes the risk of mistaking fecal accumulations for the kidneys.

The best methods of examining the kidneys are these. First, by deep pressure with the fingers, gently and yet steadily following up the slight gain which can be made

with each profound inspiration and expiration, taking care not to mistake any part of the liver or the spleen for the kidney. Second, by what Guyon calls *ballotement rénal*, which is effected by combining the first method with short taps or thrusts made with the fingers pressed firmly against the back, over the region of the kidney, by means of which it is propelled against the fingers pressing down in front. The third method is recommended by Israel, and consists in placing the patient on the side, with the knees and thighs slightly flexed, and making bimanual pressure very similar to that described by Guyon for *ballotement*.

A fourth method has been proposed by Glénard, of Lyons, which consists simply in palpating the region of the kidney between the thumb in front and the fingers of the same hand pressed up in the costo-vertebral angle.

In conducting these examinations all investigators agree that the rhythmic motion of the kidney with each inspiration can be detected, and alteration of its position, size, shape, consistency and sensibility. The detection of rhythmical motion in the kidney is a point in these examinations which it is important not to overlook, especially as the general supposition has been that the kidneys are immovable, and that motion in rhythm with the respiratory act serves to differentiate tumors connected with the intra-abdominal organs from those connected with or in the kidneys.

We cannot spare space at this time to point out all the valuable information in regard to the kidneys which may be gained by a successful palpation, as described above. But one extremely important point deserves mention. This is that, in any contemplated operation on the kidney, it must always be of great value to ascertain if the other kidney is present, and of probably normal size. Another point, which Israel has found extremely useful in practice, is that an erroneous diagnosis of floating kidney may sometimes be corrected, and a useless operation avoided by finding the kidneys where they ought to be.

In conclusion, it may be noted that this valuable method of diagnosis is not practicable in every case, and that it should always be associated with every other known method of ascertaining the physical and functional condition of the kidneys. But, with this well understood, the methods we have described constitute a very valuable addition to our means of examining the kidneys, and one which deserves the widest dissemination among medical men.

FUNCTION OF THE COCCYX IN LABOR.

It is quite impossible to over-estimate the importance of thoroughly understanding the mechanism of the passage of the fœtus through the pelvis. This dominates the whole scientific practice of midwifery, and the practitioner cannot acquire more than a merely empirical knowledge, such as may be possessed by an uneducated midwife, or conduct the more difficult cases requiring operative interference, with safety to the patient or satisfaction to himself, unless he thoroughly masters the subject.

Thus appreciating a knowledge of the mechanism of labor, we have read with much pleasure a contribution to the study of the subject by Dr. Henry D. Fry, of Washington, entitled "The Function of the Coccyx in the Mechanism of Labor" (*Amer. Journal of Obstetrics*, Dec., 1888). Dr. Fry states that obstetricians in general attribute no function whatever to this little bone, except to get out of the way of the advancing head, and thereby to increase the antero-posterior diameter of the inferior strait. It is not even supposed to possess any obstetrical importance unless it rudely refuses to be pushed aside. He believes, however, that the coccyx has a distinct function to perform and that only after it has performed it does the bone recede before the advancing head. According to Dr. Fry, the function of the coccyx in labor is to cause extreme flexion

of the head—in anterior positions of the vertex—at the inferior strait, whereby the escape of the occiput from beneath the pubic arch is facilitated, and the sub-occipito-bregmatic diameter of the head is brought in relation with the antero-posterior diameter of the pelvis, instead of the longer occipito-frontal, or occipito-bregmatic diameter. When the head reaches the inferior strait in normal labor it is not in extreme flexion. But as the head advances the brow meets with the resistance of the coccyx, its advance is arrested and the occiput descends. The resistance of the coccyx keeps up flexion until the occiput escapes from beneath the pubic arch and the nape of the neck becomes fixed against the symphysis pubis, when, since the occiput can advance no further, the force of the expulsive efforts is transmitted to the brow, overcoming the resistance of the coccyx and causing extension of the head with delivery of the brow and face.

While these views of Dr. Fry seem to be but a slight modification of the view that this last exaggerated flexion of the head is brought about by the resistance of the pelvic floor against the advance of the frontal region of the head—because the resistance of the normal coccyx must be equal to the resistance of its muscles—yet it is well to have the fact insisted upon that exaggerated flexion of the head does occur during the escape of the occiput, and prior to extension of the head. Because, while usually admitted, its bearing upon the proper management of the close of the second stage of labor is not generally appreciated. Having in mind the mechanism of passage of the head through the inferior strait and soft parts, the practitioner is enabled intelligently to manage this stage of labor, favoring flexion or extension of the head, and retarding or accelerating its advance by his manipulations as the circumstances indicate, all being done in accordance with, instead of in opposition to, the natural mechanism of labor.

HYSTERIA IN CHILDREN.

Typical examples of common diseases are easily and quickly recognized by general practitioners. It is in the diagnosis of rare diseases and of unusual manifestations of common diseases that mistakes are frequent. Thus a pneumonia of the apex has been mistaken for meningitis, and alcoholic delirium has been taken for acute mania. Such errors are often the result of carelessness rather than of ignorance; but it is at all times difficult, even for a well-read man, to keep such a comprehensive picture of a disease before his mind that he can at once recognize it, no matter how it may be obscured by unusual phenomena. This difficulty is increased when the disease in question is hysteria, in which the possible manifestations are limited only by the range of intelligence and degree of moral depravity of the patient.

Some of our readers may recollect a lecture by Charcot on Hysteria and Spiritism, which was published in the REPORTER, July 21 and August 25, 1888, and in which Charcot related in detail the histories of three children living in a penitentiary and developing hysteria under the influence of certain spiritistic exhibitions indulged in by their parents and others. There were three children, two boys and a girl. Hysteria developed in the latter in August, 1884, following a *séance* of spiritualism, in which the girl played the part of medium. At the end of the *séance* she was taken with convulsions, which were repeated from fifteen to twenty times a day, until both brothers followed the deplorable example set by their sister and developed fits of delirium associated with hallucinations.

Instances of hysteria in children, more or less similar to the one just quoted from Charcot, are not unknown in this country; but unfortunately they frequently fall under the notice of those who are unable to recognize the disease and who, perhaps, are ignorant of the fact that it may occur among children. What is perhaps a curious illus-

tration of the statement just made may be found in the report, which comes from one of the Western States, that three children in one family, ranging from six to twelve years of age, were suddenly seized with "violent paroxysms," in which "they raved like maniacs and frothed at the mouth as if afflicted with hydrophobia." It is further stated that the children had to be locked in separate rooms and that at regular intervals they went into violent convulsions, which were so severe that two or three persons were required to restrain the patients.

These symptoms may or may not have been due to hysteria, but the fact that they developed suddenly and without apparent cause in three members of one family, and that the paroxysms were alike in each and occurred at the same hour each day, is strongly suggestive of hysteria. At least hysteria is the disease first to be thought of when the symptoms mentioned as occurring in these children appear, and the diagnosis of a more serious affection should not be made until the milder one has been excluded by careful examination. The important point, after all, is—not to know whether this or that instance of sudden explosion of nervous energy is due to hysteria or not, but rather to bear in mind the possibility that it may be, and to be able to recognize it when it is.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

THE PATHOLOGY, CLINICAL HISTORY AND DIAGNOSIS OF AFFECTIONS OF THE MEDIASTINUM OTHER THAN THOSE OF THE HEART AND AORTA. By Hobart Amory Hare, B.Sc., M.D., Demonstrator of Therapeutics, etc., in the University of Pennsylvania, etc. Large 8vo, pp. 150, with 6 photolithographs. Philadelphia: P. Blakiston, Son & Co., 1889. Price $2 00.

This book contains the essay to which the Fothergill medal of the Medical Society of London was awarded March, 1888. Dr. Hare, with great industry, has collated the statistics of five hundred and twenty cases of disease affecting the mediastinum, tabulating them carefully, and analyzing them so as to make them show just what diseases occur most frequently here, what are their symptoms, and how they should be treated. He concludes that cancer is more frequently found in the mediastinal space; that abscess comes next in frequency; that sarcoma occupies the third place; and that lymphomata and lymphadenomata come next, though they are much more rare than the other forms of disease named.

His work is one of great value, as it is the most important systematic study of mediastinal disease which has ever appeared. It is written in a clear and interesting style, and is beautifully printed.

COMPENDIUM OF THE LAWS RELATING TO PUBLIC HEALTH AND SAFETY OF THE STATE OF PENNSYLVANIA, TOGETHER WITH THE DECISIONS OF THE SUPREME COURT AND COUNTY COURTS RELATING THERETO. Compiled for the State Board of Health. Large 8vo, pp. 175. Harrisburg: Edwin K. Meyers, State Printer, 1888.

The title of this paper-covered book indicates its contents. It has been published by the State of Pennsylvania for the benefit of its own citizens, and it is a work of great value for all who wish to know the present state of the laws relating to public health and the practice of medicine. Five thousand copies have been printed, and any of our readers desiring a copy should apply to the Senator or Representative of his district, or to the Secretary of the Board of Health, Dr. Benjamin Lee, Philadelphia.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

238. The Philosophy of Memory. By D. T. Smith, M.D., Louisville, Ky. From the *Practitioner and News.* 39 pages.

239. Zur Heilung der bacillären Phthise. (The Cure of bacillary phthisis.) By Dr. Louis Weigert, Berlin. From the *Internationale klinische Rundschau*, No. 51, 1888. 4 pages.

238. As might be expected from the title of Dr. Smith's pamphlet, it contains a study of the nature and operations of the faculty called memory. These are matters hard to understand, and hard to explain. Dr. Smith regards memory as the persistence of vibrations of the part of the brain which is the seat of consciousness—a formula which will mean more to some people and less to others. He develops his argument in an interesting manner; but it would be too much to say that he succeeds in making his obscure and difficult subject very clear or comprehensible.

239. Dr. Weigert has made experiments (referred to in the Reporter, November 3, 1888) which confirm the belief that the activity of certain micro-organisms is diminished by the action of heat, and that human beings can inhale dry air, heated to 150°–180° Centigrade, or 292°–356° Fahrenheit, for hours at a time, without injury. Applying this to the treatment of phthisis he has found, in an experience of fifty cases, a marked improvement in the condition of his patients, and he recommends the inhalation of highly heated dry air as a formal method in this disease. His paper contains a description of the apparatus he uses, illustrated with engravings, which make its mechanism easy to understand.

The plan proposed is sufficiently striking to attract attention; and, if such results as he claims can be obtained by other medical men, his method will prove a valuable addition to the means of combating pulmonary consumption.

CORRESPONDENCE.

Treatment of Medical Witnesses.

TO THE EDITOR.

Sir: The editorial in the REPORTER February 15, entitled: "Deception of a Medical witness," is exceedingly good and timely, and the infamous deception which was played on Dr. Kiernan should be a warning for medical experts in the future. While an honorable and upright lawyer would never descend to so base a trick, yet men who will are likely always to be found in the profession of law.

For many years I have, at times, been in the courts as an expert, yet there never was such an infamous thing attempted while I was in the witness-box. I am reminded, however, of a little episode which occurred some years ago in the trial of a case for malpractice. The late Prof. Hamilton's work on "Fractures and Dislocations" had been introduced, and admitted in evidence as a standard work previous to my entering the "box." A question was put to me, the answer to which I desired to explain, but the explanation was denied me. My opinion also was asked as to Prof. Hamilton's work being good authority, and I replied that it was. At this time the lawyer stood up and read a sentence which *appeared* to vitiate materially my testimony. He then said, "Dr., what do you say to that?" I replied: "that is not Dr. Hamilton's opinion on the point at issue." At once he stepped forward *and placed the book in my hands*, saying "read for yourself, and to the jury if you desire." Then, as the saying is, "I knew I had him." I began reading to the jury what the counsel had already read, and I continued to read. Soon he saw that the props were falling from under him, and he approached me and asked for the work. I declined, saying, that I had not yet quite fully corroborated my testimony. He then appealed to the judge (whom I knew to be very friendly with doctors generally), for an order requiring me to surrender the book. His honor declined, saying, "the counsel placed the book in the witness' possession, and asked him to read to the jury, and so long as his reading is confined to the treatment of this case, it shall remain in his possession, or until he voluntarily surrenders it." I did retain it until I was satisfied that, so far as the surgical testimony was concerned, the doctor was safe.

The expert must ever be on the alert. He must not assume to possess more knowledge than he really does. Above all things he must be *cool, self possessed, and thoroughly posted.* I will relate an instance which occurred some years ago, and where eminent counsel were engaged upon both sides, and where damages to a large amount were claimed.

Without mentioning the particulars I will simply state that the question was whether or not pus could exist in the spinal canal, previous to death, without paralysis of any kind? I stated in my testimony, that "it had been found at an autopsy, and where there had been no paralytic symptoms previous to death." On the part of the defence was an expert, very distinguished in the profession, and one who occupied the highest position possible in one of the largest institutions of this State, who had fully endorsed a certain work which had previously been introduced, and admitted as authority, and who said he was familiar with it, yet swore positively that "no authority admitted the above facts." When the case was read to him, he could only say, "it don't seem possible." This was one of those cases where too much knowledge was assumed, and where very great humiliation was manifest to all in the court room.

Yours truly,

D. COLVIN, M.D.

Clyde, N. Y.,
March 4, 1889.

Retained Placenta; Removal.

TO THE EDITOR.

Sir: About midnight of January 13, 1889, I was called to see Mrs. P., who, the messenger said, was bleeding to death. I found the patient nearly "bled out." She had been taken with flooding while in the parlor of a family that she was visiting. She had had one child, which is now six years old. On November 10, 1888, she aborted, at two and one-half months' utero-gestation, and since that event she had not had any bleeding except what she supposed was her regular monthly sickness, which occurred in December. I compressed the uterus through the abdomen, and the bleeding stopped. An examination with the finger revealed a slightly enlarged womb, a marked cicatricial line running from the anterior lip of the os uteri up the cervix, and a slightly patulous os. My diagnosis was retained placenta, although there was no dilatation of the cervix. The patient stated emphatically that such a thing was impossible, as

the physician who had attended her in the miscarriage had seen and examined the fœtus and afterbirth and assured her that everything had come away, and that she might go about as she pleased, after the ninth day.

I packed the vagina with carbolized absorbent cotton, and gave, every three hours, suppositories containing ten grains of ergotin and a quarter of a grain of extract of opium. This treatment I continued for five days, being careful to remove the tampon and give a vaginal injection of a solution of corrosive sublimate—one to two thousand—every twenty-four hours. On the sixth day I dilated the cervix with dilators and removed the entire placenta—curetting the uterine cavity and washing it with a solution of bichloride of mercury. There was at no time any offensive discharge, and the patient had no pain and no fever. In two weeks after the operation she returned to her home in Atlantic City in good health.

Yours truly,

C. H. Shivers, M.D.

Haddonfield, N. J.,
March 5, 1889.

Notes and Comments.

A Native Indian Doctor.

One of the recent graduates of the Woman's Medical College of Pennsylvania is a native Indian, Dr. Susan La Flesche, of whom Dr. Walker, in his address to the graduates, gave some interesting information. It seems that she commenced her studies of English at the school on the Indian reservation. Coming East, she continued them for a while at a boarding-school, and later at the Indian school at Hampton, Va., where she graduated in 1886, and then came at once to Philadelphia to study medicine. The impulse to a professional career was the result of a desire to see her people independent of the unskilled, and oftener indifferent, attention of the reservation doctor.

Anatomy of the Contortionist.

Dr. Thomas Dwight, in an article in *Scribner's Magazine*, April, 1889, says: What, then, is a contortionist? In the first place, it appears that a contortionist is a person who has preserved in his spine, and in some cases in his joints, the infantile condition which in most persons is merely transient. This implies a great flexibility of the spine in all directions, great powers of twisting it. It is also very likely that there are many small individual peculiarities all favoring uncommon freedom of motion. If a young boy without any of this special fitness should be trained for contortion, I think he probably would meet with some success, but never achieve distinction. So far as I am aware, children are not educated for this profession from their tenderest years, as they are for several kinds of acrobatic performances. Their capacity makes itself known by accident, from which it is fair to infer that it rests on an anatomical basis.

A Fight at the New York Maternity Hospital.

The Faculty of the College of Physicians and Surgeons of New York is investigating an exchange of blows which took place March 22, between the house physician of the Sloane Maternity Hospital and a student at the College of Physicians and Surgeons.

According to the statement of the latter and his friends, one day last week a patient was being attended by the house physician, when she clutched his arm. For this she was dealt a blow on the face. The student in question, who was standing by at the time, indignantly resented this treatment. A few days subsequently the house physician and the student met at the Maternity, and it is alleged that the former began the attack, which resulted in his getting a severe thrashing. The committee which has charge of the investigation will conclude its labors soon.

Convention for the Revision and Publication of the Pharmacopœia of the United States.

A call for a General Convention for the revision and publication of the United States Pharmacopœia, to assemble in Washington, D. C., at noon of May 7, 1890, has been issued by Robert Amory, President of the Convention of 1880. It is requested that every incorporated medical or pharmacal College, Association or Society desiring to be represented in the Convention send to Mr. Amory its corporate title and a list of its officers, addressed to the care of Dr. Edwin H. Brigham, Assistant Librarian of the Boston Medical Library, 19 Boylston Place, Boston, Mass., in order that Mr. Amory may prepare for publication, as directed by the Convention of 1880, a list of the bodies to be represented.

The Governor of Illinois on the Medical Practice Act.

In his message of January 9 to the General Assembly of Illinois, Governor Oglesby discussed the Medical Practice Act as follows:

During less than twelve years of its existence, this act has done much to protect the sick and the afflicted from charlatans and quacks; it has driven out of the State most of the ignorant, unqualified and unprincipled men who were preying upon the miseries of their fellows; and it is not too much to say that it has elevated and ennobled the practice of medicine, both in the State and throughout the country. The methods of medical education have been improved as a consequence, and the standard of attainments required of the physician who is to deal with the weighty questions of health and disease, and of life and death, is being steadily raised. The Illinois State Board of Health is now regarded as the pioneer in this work, and it is quoted as authority both in this country and abroad. Since the passage of the amended act—in force July 1, 1887—the Board has refused licenses to itinerant vendors of nostrums, with show accompaniments. The amount of these licenses would aggregate over $20,000, but the sum which the itinerants would fleece from the credulous would figure up hundreds of thousands a year.—*Indiana Medical Journal,* March, 1889.

Army Medical Board.

An Army Medical Board will be in session in New York City, N. Y., from May 1 to 31, 1889, for the examination of candidates for appointment in the Medical Corps of the United States Army, to fill existing vacancies, of which there are now seven, and an additional one will occur in July. Persons desiring to present themselves for examination by the Board will make application for the necessary invitation to the Secretary of War, before May 1, 1889, stating the place of birth, place and State of permanent residence, and enclosing certificates based on personal knowledge from at least two persons of repute, as to American citizenship, character and moral habits. Testimonials as to professional standing, from Professors of the Medical College from which the applicant graduated, and of service in hospital from the authorities thereof, are also desirable. The candidate must be between 21 and 28 years of age, and a graduate from a *Regular Medical College,* evidence of which, his Diploma, must be submitted to the Board.

Further information regarding the examinations and their nature may be obtained by addressing John Moore, the Surgeon General, U. S. Army, Washington, D. C.

The Medical Examiners' Bill.

The Philadelphia *Ledger,* April 1, 1889, refers to the remarkably fair and liberal bill providing for State examination of practising physicians, which was introduced into the Pennsylvania House of Representatives at the instance of the Medical Society of Pennsylvania, and quotes as follows from its issue of March 20: "A claim is put forward by the doctors of several of the 'new schools' for minority representation in the Examining and Licensing Board. That is a proper claim; it should be conceded and is conceded in the bill as it stands. But the trouble seems to be that, while the 'old school' doctors are willing to concede 'minority *representation,*' they are not ready to agree to minority *control.* They are right about this, for the amendment proposed by the 'new schools' of medicine might be easily made to give such a preponderance to less than *one-fourth* of the total number of medical practitioners in the State as would enable them or their representatives in the State Board to overrule the representatives of the other three-fourths." With reference to the amendments made to the Bill, which give an equal representation to all the schools, it says: "It will be observed that since the above article was published the Legislature has so amended the bill that the representatives of three-fourths of the doctors of the State cannot by any possibility be a majority of the Board, and that the representatives of one-fourth may, if united, control the Board. This is all wrong; yet so anxious are the leading physicians of the city to have State examinations that they have agreed to accept the amended bill, though it is unfair to them; but they ask in return that graduates of medical schools be required to attend a four years' term. This would force the higher education of physicians, and is a course which the better colleges would be glad to have made compulsory. But the Legislature, without regard to 'old school' or 'new school,' ought to make the bill a fair one by reconsidering the amendments made, and should certainly join heartily with the best physicians to raise the standard of doctors admitted to practice in the State so as to get rid of quacks and pretenders in all 'schools,' old and new."

NEWS.

—Scarlet fever is prevalent at Marlborough, a hamlet near Newburgh, New York.

—The Texas State Medical Association will meet in San Antonio, Texas, April 23–26, 1889.

—The Hospital Collection Fund of New York City amounted to $52,033.40 during the year 1888.

—Dr. H. C. Wood will deliver the annual address at the coming commencement of the Yale Medical School.

—Dr. R. P. Howard, Dean of the Medical Faculty of McGill University, Montreal, died in Montreal, March 28.

—The Alabama State Medical Association will meet in Mobile, Tuesday, April 9, 1889, and continue in session four days.

—The Nineteenth Annual Meeting of the California State Medical Society will be held at San Francisco, April 17, 18 and 19, 1889.

—The Thirty-ninth Annual Meeting of the Illinois State Medical Society will be held in Jacksonville, Tuesday, May 21, 1889.

—The Eleventh Annual Meeting of the Louisiana State Medical Society will be held in New Orleans, Tuesday, April 9, 1889.

—The Twenty-seventh Annual Meeting of the Mississippi State Medical Association will be held in Jackson, Wednesday, April 17, 1889.

—The Thirty-ninth Annual Meeting of the South Carolina Medical Association will be held in Charleston, beginning Wednesday, April 10, 1889.

—The Western Pennsylvania Medical College held its commencement March 28, and conferred the degree of Doctor of Medicine upon thirty-six graduates.

—Dr. Thomas J. Mays will deliver his third lecture on Pulmonary Consumption a Neurosis, Friday evening, April 12, 1889, at 8 o'clock, in the Philadelphia Polyclinic, Broad and Lombard Streets. Physicians are invited.

—The following numbers of infectious diseases and deaths were reported in New York City for the two weeks ending March 19 (*New York Med. Journal*, March 23, 1889): Typhoid fever, 18 cases and 5 deaths; scarlet fever, 728 cases and 95 deaths; cerebro-spinal meningitis, 4 cases and 1 death; measles, 425 cases and 40 deaths; diphtheria, 403 cases and 91 deaths.

OBITUARY.

EDWARD T. BRUEN, M.D.

Dr. Edward T. Bruen, of Philadelphia, Assistant Professor of Physical Diagnosis at the University of Pennsylvania, died March 31, of pneumonia, after an illness of less than a week.

Dr. Bruen was born in Philadelphia in 1851. In early life he attended private schools under the direction of his father, and later entered the University of Pennsylvania, from which he was graduated in medicine in 1873. In 1874 he was elected one of the visiting physicians to the Philadelphia Hospital, and has been a lecturer in the Spring courses at the University of Pennsylvania for a number of years. In 1880 he was elected Demonstrator of Clinical Medicine, and in 1884 was appointed Assistant Professor of Physical Diagnosis in the same institution. He was also a visiting physician to the German Hospital. His contributions to medical literature were numerous; his "Handbook of Physical Diagnosis of the Heart and Lungs," has passed through two editions. He was a member of the Association of American Physicians, of the American Climatological Society, and of the Philadelphia County Medical Society, and of other medical societies. He leaves a wife and two children.

Dr. Bruen's illness was sudden in its onset and proved fatal rapidly. Not long before he was taken sick he delivered the lecture on Nervous Dyspepsia, which appears in this number of the REPORTER, and it has a melancholy interest from the fact that it is probably the last manuscript that he revised before his death.

JOHN SWINBURNE, M.D.

Dr. John Swinburne, formerly Health Officer of New York City, died in Albany March 29, 1889. Dr. Swinburne was born in Denmark, Lewis county, in 1821, and was graduated from the Albany Medical College in 1846. He was soon made Demonstrator of Anatomy in the College, holding that position four years. In 1861 he volunteered, without pay, as an army surgeon, and served with distinction. In 1864 he became Health Officer of the Port of New York, and during his term he established the quarantine service which now exists there. While abroad with his family in 1870, he took charge of the American ambulance service in Paris during the Franco-Prussian war.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

THERE IS A PEPSIN

WHICH IS UNIFORMLY ACTIVE, PERMANENT, AND RELIABLE,

IT IS "FAIRCHILD'S."

This Pepsin will not spoil, will not become soft and sticky in the vial, even if left long uncorked.

Fairchild's Pepsin will not "gum up" if dispensed in powders, plain, or with the drugs usually combined with pepsin.

Fairchild's is not a partial peptone, and has none of the well-known characteristics of peptone.

Fairchild's is the pioneer pepsin, it showed the way. It "got there" early.

Its activity has never been exaggerated.

All this time, whilst other manufacturers were still offering the high-dilution saccharated and amylated article, Fairchild's Pepsin was steadily making its way on its merit. Now, no one ventures to ask a hearing for these *placebo-pepsins*.

When physicians now prescribe "pepsin" they mean pepsin—not milk sugar, and pepsin.

All these years, Fairchild's Pepsin was always and everywhere found to do just what was claimed for it—in spite of the attitude, genuine or assumed, which held that all "claims" about pepsin must be taken with a liberal discount.

Every *bona fide* test demonstrated its reliability.

We have never found it necessary to explain or excuse any deficiency or inaction as due to "deteriorated" specimens.

Fairchild's will not disappoint the prescriber under any condition proper for pepsin.

With Such a Record Fairchild's Pepsin is a good one to stand by.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

PHILADELPHIA

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

CLINICAL LECTURE.

DIGITAL DILATATION OF THE PYLORUS.[1]

BY J. M. BARTON, M.D.,
PHILADELPHIA.
SURGEON TO THE JEFFERSON COLLEGE HOSPITAL.

(Reported for the MEDICAL AND SURGICAL REPORTER.)

Gentlemen: The patient I bring before you is one who is slowly starving to death from obstruction to the pyloric orifice of her stomach. She now vomits nine-tenths of all the food she takes, and has lost more than one-third of her weight during the last year. She is 48 years of age, is a patient of Dr. Adams, of Vineland, New Jersey, and was in perfect health until five years ago.

During 1884, 1885 and 1886, she suffered with the symptoms of gastric ulcer—pain and vomiting immediately after eating, the vomiting occurring as often as six times in the twenty-four hours. She lost greatly in flesh and had two severe hemorrhages, vomiting at one time, she states, nearly a gallon of dark-colored blood; this amount is probably greatly over-estimated. In 1887, all the symptoms of the disease left her, and for the greater part of the year she enjoyed excellent health, weighing, in January, 1888, one hundred and forty-three pounds, which was more than she had ever weighed in all her life.

During the last year, however, she has been very ill, with symptoms of pyloric obstruction, and she has lost flesh rapidly, weighing a few days ago only ninety-three and one-half pounds. She now vomits but once in twenty-four or forty-eight hours. This occurs when she lies down at night, and it is not accompanied by nausea. It is usually from one and a half to two quarts in quantity, and measures nearly and sometimes quite as much as all the nourishment taken since the preceding act of vomiting, twenty-four hours before. Many articles

[1] Delivered before the class of the Jefferson Medical College, February 16, 1889.

taken during the day can be recognized when vomited at night; indeed, she states that she has occasionally been able to recognize articles eaten as long as two weeks before. As she takes her meals she feels that her stomach is becoming more and more distended, and when she lies down at night, gravity brings the contents of her stomach into her throat, and they are then vomited. Her bowels are obstinately constipated, acting only once in twelve or fourteen days, and then only after frequently repeated large injections; purgatives administered by the mouth produce no effect. She has lately been able occasionally to feel a small tumor about the size of a hazel nut, two inches to the right of the umbilicus.

Her stomach is greatly enlarged; we have determined its size by distending it with carbonic acid gas developed from half of a Seidlitz powder, giving the soda and the acid separately. Her stomach reaches as low as the umbilicus and as far as the small tumor, though we cannot say that the tumor is connected with the stomach. If the vomiting depended upon inflammation of the stomach or upon an ulcer, it would probably occur immediately after eating. If it depended upon indigestion, it would occur from half an hour to an hour after taking food; but when it occurs, as here, only when the stomach is fully distended, is influenced by gravity, is not accompanied by nausea, and when, moreover, the matters vomited consist of several preceding meals, and there is a desire for food immediately after vomiting—we may be sure that it is due to some mechanical obstruction situated at or near the pylorus.

Now this mechanical obstruction may be due to a new growth, as some form of cancer, or it may be due to stenosis of the pylorus from contraction following the healing of an ulcer, and the history points distinctly to this latter condition. For, during 1885 and 1886, her symptoms were markedly those of gastric ulcer; under proper treatment the patient not only recovered but increased in weight until she was heavier than ever before. After a year of perfect health, vomiting, of a totally different character, occurred, being now distinctly obstructive. The history is too long for the trouble to be cancer; the average duration of life in gastric cancer, according to Brinton, is one year; the maximum duration, according to Bartholow, is three years; in the present case it is now five years since the first hemorrhage. The complete recovery two years ago and the subsequent return of symptoms is not the history of cancer. The size and mobility of the tumor, if the tumor has anything whatever to do with the stomach and its symptoms, do not indicate cancer of five years' duration.

The character of the hemorrhage is also against the diagnosis of cancer. In cancer small amounts of blood are lost quite frequently, whereas in ulcer the hemorrhages are large and occur at long intervals. The absence of diarrhœa caused by an ulcerating cancer, and her freedom from any hectic or cachectic appearance, are also points against the probability that the disease is cancer.

The diagnosis is, therefore, non-malignant stricture of the pylorus, due to cicatricial contraction after the healing of an ulcer. We must be prepared to treat the obstruction even if it should not be of the character that the weight of evidence is in favor of. It might be a malignant tumor of the small bowel; if it should be so, and if it be far down, I shall excise that portion of the bowel as I did in a case I brought before you some time ago. After excising the bowel I shall make a temporary artificial anus and place Dupuytren's enterotome at once in position for its cure. If it be a tumor of the bowel high up, an artificial anus can not be made, as the patient would perish of inanition. I should then excise the bowel and growth and bring the divided ends of the bowel together, performing what is called a circular enterorrhaphy. If it should prove to be an extensive but non-adherent cancer of the pylorus, I might do a pylorectomy, excising the pylorus and growth and bringing the stomach and duodenum together. If it should be malignant and extensively adherent, I shall do a gastro-enterostomy, making an opening in the stomach and in a contiguous layer of jejunum, bringing the two in apposition with the aid of these two decalcified bone plates, which I have here. If it be malignant, but of recent origin and still limited to the mucous membrane, I shall open the stomach and with the curette scrape away the mass after the method of Bernay's, of St. Louis.

But if it prove to be a simple stricture, as I hope and think it will, I will open the stomach and will then stretch the pylorus with these uterine dilators, these œsophageal forceps, and with my fingers. Will the pylorus stay dilated? Prof. Loreta, of Bologna, who first performed this operation, in 1882, has had a number of permanent successes; Mr. Hagyard, of England, reports upon a case fifteen months after

operation, and states that the patient is still in admirable condition and there is no symptom of return. If it were not for these statements I should fear from analogy that it would re-contract, and I should then prefer the operation of Heineke, which consists in making a longitudinal incision, two inches long, through the pylorus, and in sewing it up transversely.

I shall slightly modify in two particulars the operation as performed by Loreta. He makes an incision five inches long on the right side of the middle line, from a point one inch below the xiphoid cartilage to one just below the cartilage of the ninth rib, and he makes the opening in the stomach close to the pylorus. In a case upon which I operated in this hospital about eighteen months ago I found a small median incision through the abdomen answer every purpose and possess many advantages. As the tissues close to the pylorus are apt to be, and were in my previous case, thickened and infiltrated with inflammatory deposits, I shall make the incision in the stomach several inches distant from the pylorus.

The abdomen of the patient was prepared yesterday by washing it with turpentine, soap and water, and corrosive sublimate solution; cheese-cloth wet in the latter solution was then bound over the field of operation, and it is still on. The patient's stomach was washed out this morning with a solution of biborate of soda; the fluid was pumped in and out a number of times until it came away quite clear. She is now under chloroform, which I prefer to ether, as there is much less danger of its causing vomiting, which would endanger the result of the operation.

The hands and instruments being prepared antiseptically, and the field of operation surrounded by towels wrung out of carbolized water, I make a small median incision about three inches in length terminating just above the umbilicus; the cavity of the peritoneum is soon reached, clamp forceps having been placed upon all vessels as they spurted. The stomach is directly beneath the incision; it is readily distinguished from the transverse colon by the thickness of its walls and by the fact that the omentum hangs from its lower edge. The pylorus even from the outside is markedly contracted and irregular on its surface; there is no tumor here. Passing my finger to the region occupied by the tumor that we felt from the outside, I readily find it and bring it to the wound; it is evidently a scybalous mass—indeed, the entire colon is full of smaller ones; they need no attention.

Three inches from the pylorus the wall of the stomach feels quite healthy. I now fold the anterior wall of the stomach transversely, midway between the greater and lesser curvatures, and with a pair of sharp scissors make an incision about one and a half inches in length. I now introduce my index finger and feel for the pylorus; this movement produces some retching, which forces most of the stomach out of the wound. I will keep it here as it will be more convenient and there will be less danger of contaminating the abdominal cavity. With my finger in the stomach the pyloric opening is readily felt; it is about one-fourth of an inch in diameter, though its margins are quite hard. As I am unable to push my finger through it I introduce this small pair of uterine dilators beside my finger, and pass the blades through the small pyloric opening. By using considerable force I dilate the orifice until one finger enters, but the second will not until I again introduce the dilators and this long pair of œsophageal forceps, when I am able to introduce two fingers and to separate them slightly. This I will be satisfied with, though Loreta says he separated his fingers three inches. Mr. Hagyard, who had the first successful case in England, did not dilate the opening nearly so much, and McBurney lost one of his cases from hemorrhage following a rupture of the mucous membrane produced while stretching the pylorus.

There has been no bleeding from the wound in the stomach, though in several of the reported cases there was very free bleeding when the stomach was incised. The wound here being much further from the seat of the disease than it is usually made may account for the small amount of blood lost. I will now close it by first bringing the edges of the mucous membrane together by a continuous suture of fine silk, and then bring the peritoneal surfaces in contact by the continuous Lembert suture.

As there is no blood in the abdominal cavity neither irrigation nor drainage will be necessary. The stomach is now washed, the wound in it again examined, and it is returned to the abdominal cavity. The abdominal wound is now closed and dressed in the usual manner.

The operation of digital dilatation of the pylorus was first performed by Loreta, of Bologna, on September 14, 1882. Up to 1884 he had reported four cases with two recoveries and two deaths. Since then he

and other Italian surgeons have performed a number of operations with varying success. It has been rarely performed in Germany, England or America. The first successful case in England was published in 1887. I have as yet found only four cases reported in America, including a previous one of my own; they all ended in death.

Note by Reporter.—The patient vomited about four ounces of blood, half an hour after the operation; but there has been no vomiting and no nausea since. She was nourished by the rectum until the fourth day; from then until the fourteenth day she was fed upon peptonized milk and broths; after the seventh day she took from forty-eight to sixty ounces of liquid nourishment in the twenty-four hours. Since the fourteenth day she has been fed upon a carefully selected solid diet. On the fortieth day after the operation she was able to eat eggs, mutton-chops, oysters (raw and stewed), beef, chicken, lamb, potatoes, cream toast, bread and butter, milk and coffee. Her temperature has never been over 99° nor under 98° Fahr., since the operation. The abdominal stitches were removed on the ninth day. The patient is now able to walk about, is much stronger, and weighs one hundred and sixteen pounds. For the first two weeks after the operation her bowels were moved every other day by the injection of one drachm of glycerine. They now move naturally every day.

SCURVY.[1]

BY FREDERICK P. HENRY, M.D.,
PHILADELPHIA.
PHYSICIAN TO THE PHILADELPHIA AND JEFFERSON COLLEGE HOSPITALS.

At the present day examples of this disease are rarely seen, and there can be no doubt that its frequency even in former times was much overrated. In the older medical works, the term "scorbutic" was very loosely employed, and the same criticism applies to popular works of fiction of the early part of this century. The writers of these books doubtless obtained their notions concerning this subject from the current medical literature. Readers of Dickens will surely recall the "scorbutic youth" who made himself so conspicuously disagreeable at Bob Sawyer's celebrated supper, and whose countenance was probably the seat of an eruption of acne. This and other skin eruptions were at that time supposed to be of a scorbutic nature; an opinion which is without scientific foundation.

I believe that I am acquainted with the entire literature of this subject for 1888, and it is exceedingly scanty. Besides three cases which I made the subject of a clinical lecture, published in the MEDICAL AND SURGICAL REPORTER, June 16, 1888, two have been reported by Variot[1] and one by Barkas.[2] An elaborate article on the "Occurrence of Scurvy among Troops and its Prevention," appeared in the *Practitioner* for May of the same year. In the course of it, its author, J. Hickman, remarks that the occurrence of a single case among troops "shows negligence, and is a reproach to the authorities." I cannot accept this statement without a word of explanation. A soldier, a prisoner, an inmate of an almshouse, or a hospital patient may be supplied with anti-scorbutic articles of food, and yet develop scurvy, because he does not eat them. Quite recently I was called to attend a rapidly growing boy, sixteen years old, who had gradually become weak and anæmic, and whose gums, on examination, I found to be decidedly tender and spongy. He had a comfortable home and was supplied with an abundance of nutritious food, but, as his mother told me in reply to my questions, he lived almost solely upon bread and meat.

The two patients I bring before you this morning owe their disease to the fact that they have steadily refused to eat potatoes, although abundantly supplied with them. The potato is one of the best of anti-scorbutics, and is believed to derive this property from the potassium which it contains in large amount. The opinion that potassium is a highly anti-scorbutic substance, and that its absence from the food is one of the causes of scurvy, was first announced about forty years ago, by Garrod, and was adopted by Liebig.

The diagnosis of a case of primary scurvy presents no difficulty to one who has closely observed a single well-marked case of the disease; but secondary cases, *i.e.*, cases occurring in the course of another disease, are very apt to be overlooked. The patient being already confined to bed, the pains on walking, so great in the primary forms, are unperceived, while the increasing feebleness is attributed to the primary affection. Lasègue and Legroux, who studied nearly one hundred cases of scurvy in the central infirmary of the prisons of Paris, during the

[1] Delivered at the Philadelphia Hospital, March 16, 1889.

[1] *Le Bulletin Méd.*, September 19, 1888.
[2] *Australian Med. Gaz.*, January 15, 1888.

siege of that city by the Germans in 1870, state with reference to their cases of secondary scurvy, that many of them would have been overlooked but for their daily careful search for its manifestations in *all the patients* under their care. The patients before you did not present themselves for treatment, but were recognized as cases of scurvy by one of the resident physicians, who systematically went through the "out wards" looking for signs of scurvy. The symptoms are well marked in both cases. In one, the gums at the time of admission were swollen to such an extent as almost to conceal the incisor teeth. In the other, the affection of the gums, though well marked, is not so extreme as in the first case. In both, as you observe, there are large subcutaneous extravasations of blood on the anterior surfaces of both tibiæ.

The influence of the mind over the body is often referred to in general terms, but seldom with special reference to the nutritive functions. Depressing emotions, whether by direct nervous action upon those functions, or indirectly by impairing the appetite, certainly predispose to scurvy. It is even believed by Barkas that the prevalence of scurvy among the Australian shepherds is in part due to their monotonous solitary lives. In their case, however, the diet, in my opinion, is all sufficient to account for it, for it is composed "solely of tea, salt beef, and 'damper.'" It is scarcely necessary to say that the emotions of an "out-warder" are depressing, for the very fact of his entrance here announces that he has abandoned hope.

The treatment of these cases will be almost exclusively dietetic. They will be supplied with onions, potatoes, and lemon juice—the best of anti-scorbutics. I can say this much with reference to their treatment, but no more, since neither of them is under my care. I am indebted to Drs. Tyson and Walker, in whose wards they belong, for the opportunity of showing them to you this morning.

They are both anæmic, and in one the precise degree of the anæmia has been ascertained by Dr. Hamill, who examined the blood with Gower's instruments. The corpuscles numbered about 4,000,000 per cubic millimeter (80 per cent. of the normal), and the coloring matter was reduced to 60 per cent. of the normal. Chalybeates are therefore indicated, and an excellent mixture in such cases is one containing the tincture of the chloride of iron and the fluid extract of ergot.

COMMUNICATIONS.

LAPAROTOMY FOR TUBERCULAR PERITONITIS, WITH REPORT OF ONE CASE.[1]

BY GEORGE ERETY SHOEMAKER, M.D.,
PHILADELPHIA.

The treatment of tubercular peritonitis by laparotomy has been attempted by many operators, but the cases are not yet sufficiently numerous, nor their after-histories sufficiently well recorded to make the chapter a closed one; and every case, if reported with its peculiarities, may help to clear up some obscure points. As will presently be pointed out, the results are probably not as absolutely certain as some writers apparently imagine, though they are remarkable.

The following case is reported at too early a date (five months) after operation to be called successful, except in one sense. To be sure, the patient was rapidly sinking; she made a prompt recovery from the operation, she considers herself well, and is working as a laboring woman; but there has been some return of fluid. This, however, is now apparently diminishing, and may disappear. It is tempting to put down operations as "recoveries" and "successes," but it is the after-histories which are important to the patients; while it is certainly exasperating to one who would study the truth of statistics, to find in so many reports the latest information dating from one or two weeks after the knife is used, with the indefinite word "recovery" following.

The case is as follows: Mrs. G., 23 years old; no tubercular family history; the patient has two healthy children, and another, of low vitality, still at the breast. She considered herself healthy until five or six weeks before coming under observation, the first irregularity noticed having been an enlargement of the right iliac region, which soon became bilateral. She never had noticed any hard tumor. When first seen she complained chiefly of abdominal distention. There was slight dry cough, and some pain in the back and in the right ovarian region, with a feeling of bearing down. She moved about freely and seemed fairly well, except for pressure symptoms; the temperature was 100.4° in the evening; there was slight loss of weight; no tenderness; bowels acted normally; menses had been normal, but

[1] Read before the Obstetrical Society of Philadelphia, March 7, 1889.

for two or three months they had appeared every two weeks, but were painless, increased in amount, with occasional appearance of blood in the intervals.

The examination showed the abdomen to be of the size of the belly in pregnancy at term; the walls were extremely tense, owing to the rapidity of the distention. No tumor was found; no coronal resonance; fluctuation was very distinct; dulness irregular in outline; there was a large external rectocele; the uterus was small, forward, fairly movable, independent as far as could be made out; nodules of the size of mustard seed were distinctly felt through the rectum in the peritoneum of the recto-uterine pouch. The urine was normal.

The probable diagnosis of ascites from tubercular peritonitis was made in the absence of heart and kidney lesion; pregnancy with hydramnios being excluded by the condition of the uterus; and there being no sign of liver disease. There was sufficient floating of the intestines, taken with other signs, probably to exclude the presence of a large ovarian cyst; though in some cases of extensive adhesion of the bowel and encysting of fluid, this differential diagnosis cannot be made. The short duration, about six weeks, did not favor, though it did not by any means exclude, a tubercular origin.

The history of an early unilateral swelling made it impossible to exclude absolutely a small malignant growth in the right side, but the absence of any sign of hardening accessible by vaginal touch made this unlikely. The presence of nodules in the peritoneum behind the uterus, first pointed out to me in consultation by Dr. H. A. Slocum, suggested three things: papilloma, tuberculosis, and malignant disease of the peritoneum. The presence of fever with loss of flesh was against the former; while the temperature, the slight, dry cough, the small, regular peritoneal nodules, pointed strongly to tuberculosis, especially in the absence of decided pain. As orthopnœa and insomnia from embarrassment of respiration rapidly developed, abdominal section was performed, although the patient was menstruating. The operation was performed for the relief or cure of tubercular peritonitis. A two-inch incision was made; the peritoneum where cut was one-quarter of an inch thick, and grayish-red; the fluid clear, highly albuminous, abundant. Everything in the abdomen felt as though plastered together with curdy exudate, while an enormous number of mustard-seed-like nodules studded the parietal and visceral peritoneum alike. Web-like adhesions were general but easily broken down, except in the right iliac region where denser adhesions and matting of the bowels had doubtless given rise to the patient's idea of early unilateral swelling. The Fallopian tubes were convoluted and slightly enlarged, but did not require removal; the ovaries and uterus were studded with tubercles, but not much altered in size. Nodules could, of course, plainly be felt behind the uterus, where they had been found before the operation. The visceral peritoneum was thickened, grayish-red, rough, injected. The point of the finger applied at any point would cover several nodules. Boiled-water irrigation was employed. No medicated application was made to the peritoneum; a glass drainage tube was used, and a plain absorbent-cotton dressing. Perfect cleanliness was maintained throughout by ordinary aseptic methods. Several pints of serum escaped from the tube during the first twelve hours; an annoying cough ejecting it so as to soil the dressing in spite of the nurse's care. The flow ceased and the tube was removed in forty-eight hours. Prompt recovery followed. The cough had disappeared by the thirteenth day, and the temperature, slightly elevated before the operation, remained normal after the fourth day.

Dr. J. P. C. Griffith kindly examined the lungs and confirmed the opinion that there was no definite sign of tubercular change there. About two months after the operation, there was some distention of the abdomen, probably from encysted fluid, though fluctuation could not be made out. This has since decidedly lessened in amount, and the patient has never been aware of its presence. Now, five months after the operation, she considers herself absolutely well. There is no hernia. It is the history of some cases that there is a temporary moderate reaccumulation of fluid, which is afterward absorbed. In other cases the belly refills rapidly and the case becomes as bad as before. At least one patient has been opened a second time for the ascites, without, however, effecting a cure.

The diagnosis of tubercular peritonitis is often very difficult, and in many cases it can not be made, especially in the absence of signs of tubercular trouble elsewhere.

Greig Smith,[1] referring to encysted effusions, says that it is "impossible to diagnose them with certainty." Again he says: "In

[1] Abdominal Surgery, p. 107.

many cases encysted dropsy of the peritoneum can not be diagnosed from ovarian cyst." The age of the patient is not significant, as it occurs from infancy to old age. Mr. Frederic Treves[1] operated on a child fourteen months old, death following in a few weeks.

The method of exclusion which must be adopted will not serve to eliminate some forms of pressure on the portal vein; nor, as has been said, will it separate papilloma or malignant disease of the peritoneum with certainty.

As an aid to the diagnosis the examination of the peritoneum in Douglas's *cul-de-sac* should always be made. This is the only point in the body, in such cases (bimanual examination being impossible from distention), at which two peritoneal surfaces can be rubbed one upon the other by the finger. The cases must be very rare where a delicate examination, or indeed any, can be made by picking up the abdominal wall. Whether or not tubercles are always to be found, if anywhere, in the recto-uterine *cul-de-sac* is not known, for no records of examination of this locality have been observed. In one other case the writer has found them. It is suggested as a point worth noting in the future. Certainly if distinct nodules can be felt here the case is not one of ascites solely from mechanical causes, and exploratory laparotomy would be more than justifiable.

The statement sometimes made that exploratory incision is almost devoid of danger is not as true in tubercular peritonitis as in the cases in which the peritoneum is healthy; especially as these cases are too widely scattered to reach the few most skillful men. As far as the writer is able to learn eight patients have been operated upon in this city, and two have not recovered from the operation. Taking the whole of the United States together, 35 genuine cases with 6 deaths are known to the writer; a mortality immediately following operation of 17.1 per cent. Excluding deaths in cases in which peritonitis was present before operation, the immediate mortality in exploratory operations (non-malignant) collected by Dr. J. M. Baldy,[2] is not quite 7 per cent.

The operations collected in Europe by Kümmell,[3] who has presented the most recent article on the subject, are 39.[4] He states distinctly that only two of these died as the result of the operation, though he is quoted by more than one American writer as reporting 6 deaths from operation on a previous occasion.

Fehling, of Basel, reports[1] 6 deaths among 29 cases operated upon. Another report[2] gives 28 cases, of which only 24 were operative successes. As the cases, though not all published in detail, are probably the same, the discrepancy in death percentage may perhaps be accounted for by a difference of opinion as to what constitutes a recovery from the operation.

In regard to the effect of operation on the condition of the patient, it may be said that there are a large number of carefully observed, *bonâ fide* cures reported; while marked temporary improvement almost invariably occurs in cases which do not succumb to the operation. Improvement would naturally follow from evacuation of the fluid, with relief to the heart and kidneys. But it must also be said that too many cases are reported as "cured" at a very early period after operation. It is unfair to take only a portion of the world's cases for analysis, and the writer is fully aware of the unreliability of statistics; but the following short analysis of American cases is offered as giving a fair general idea of the question of results: Of the 35 cases collected (reported and unreported) 6, or 17.1 per cent., did not survive the operation; 4 died with recurrence within six months; 14, or 40 per cent., are reported "cured" after periods ranging from *one month* to two and a half years. In other words, the "cures" known to exceed six months in duration are 11, rather less than one-third of the cases. Eight out of 29 cases studied by Fehling[3] lived one year.

The writer wishes to be understood as maintaining no argument against laparotomy in such cases; he is a warm advocate of it; the desire is to come nearer to the truth in probable prognosis, and to emphasize the fact that there are some cases in which no practical benefit can be looked for. Even if there were no hope of cure, other advantages justify operation. One writer on this subject has aptly said:[4] "The establishment of the diagnosis beyond question and intelligent treatment based thereon, together with relief of pain and freedom from opium,

are advantages of incalculable value; and give hope and comfort in a desperate, painful, and hopeless disease."

Kaulich[1] has pointed out that cure is most likely to result in cases in which the onset is insidious, the progress slow, without much rise in temperature; and where ascites is abundant from an early period.

There are other cases of tubercular peritonitis, perhaps more correctly styled abdominal tuberculosis, in which there is no ascites, the belly is scaphoid, and intestines and organs are matted in one inextricable mass; where mesenteric glands have become large tubercular masses, and where every abdominal structure is studded with cheesy nodules from the size of a pea to that of an egg. Such a case, occurring in the male, died about six years ago under the observation of the writer. Laparotomy was not attempted, nor would it probably have been of the slightest service. At the autopsy the belly seemed almost absolutely dry, and there were no surfaces in contact which were not tightly adherent. Such patients if operated upon usually die soon afterward, but there are a few cases reported in which temporary comfort was derived in this way. Cases occurring in males are rare. Fehling (*loc. cit.*) speaks of two.

Cure may be anticipated where effusion is abundant and where there are no deposits outside the peritoneum. That the tubercles are real has been proved conclusively in a number of cases by microscopical demonstration and the cultivation of bacilli (Hartwig, Marcy). That they disappear absolutely from localities where they existed at the operation has been proven by autopsy in several cases (Hirshfield).

The reason for their disappearance is not known, and will not be until we know more of the life-history of tubercle. Some of the theories are: (*a*) That they become encysted or encapsulated and are absorbed; (*b*) that the hyperæmia of the peritoneum from withdrawal of ascites leads to their "strangulation"; (*c*) that the fluid is a source of irritation in itself [but aspiration is not as effective as laparotomy]; (*d*) that the majority of bacilli are drained off with the fluid and the remainder are overwhelmed by the vitality of the peritoneum.

This subject was discussed by Dr. Ely Van de Warker[2] before the American Medical Association in 1887. Hegar also has thoroughly considered the whole subject of genital tuberculosis in women,[1] and has collected much material.

The following conclusions seem reasonable to the writer from data at present available.

1. The diagnosis is usually difficult and frequently impossible. Fortunately it is not always necessary.

2. The best known treatment is laparotomy, with simple water irrigation and drainage. The local use of iodoform, iodine, carbolic acid, etc., gives no better results.

3. The operation mortality is considerably higher than that of exploratory incision when the peritoneum is not diseased.

4. A considerable number of complete and permanent cures, anatomical and symptomatic, of genuine tuberculosis of the peritoneum, are on record. The reason for the cure is not known.

5. The most that can be looked for in more than one-half of the cases is temporary relief; but this is usually decided and far outweighs the risk of incision.[2]

CASE OF LARGE CEREBELLAR, AND SEVERAL SMALLER CEREBRAL HEMORRHAGES.

BY THEODORE DILLER, M.D.,

ASSISTANT PHYSICIAN IN THE STATE HOSPITAL FOR THE INSANE, AT DANVILLE, PA.

The following case is interesting viewed from several standpoints, and I think it is quite worthy of being noted. The history which accompanied the patient, though meagre and unsatisfactory, is still of value in the study of the case.

Mrs. D——, widow, admitted into the Danville Hospital, June 4, 1887; married 22 years ago; had one still-born child seventeen years ago; supposed cause of insanity, domestic troubles and money matters; prominent symptoms consist of incessant talk of a rambling sort. She is said to have had attacks of epilepsy or apoplexy several years ago. When irritated she has threatened to jump out of the window. For more than a year there has been alternate mental depression and excitement. Various physicians have been employed and different remedies have been

[1] Die Entstehung, Diagnose u. chir. Behandlung d. Genitaltuberculose des Weibes. Stuttgart, 1886.

[2] NOTE. The thanks of the writer are due to many gentlemen for late reports of operation cases, and also for several unpublished cases.

tried, but with no good result. When admitted her general health was impaired, for which a tonic was ordered. She had various erratic ideas concerning brain clots, her ideas being often disjointed and mixed.

On June 15, 1888—about a year after her admission to the hospital—her powers of locomotion were slowly becoming impaired. On her arrival here she was able to play some old familiar airs on the piano, but now she was unable to strike simple chords. Her language and power of expression had altered quite materially. She was very fond of creature comforts.

By Nov. 1, 1888, the patient had a peculiar gait, taking short steps, with her feet dragging on the floor. She had many symptoms which appeared to be of an hysterical character; for example, she asked if she were not fatally ill, and whether she would live until morning. She asked for a piece of brown bread, or a soft-boiled egg, with as much earnestness as though it were a matter of momentous importance. She spoke quickly, and in a jerky manner. She often stopped abruptly in the midst of a sentence and with a look of earnest appeal on her face would say: "What is it? What is it?" If the word was supplied, her face would at once light up, and she would be profuse in her thanks. She referred all her trouble to her brain, often saying: "There is a weakness" (indicating her head). Since June, 1887, nineteen convulsive seizures had been noted as follows: In 1887, June, one; July, none; August, two; September, none; November, none; December, two. In 1888, January, none; February, none; March, three; April, none; May, two; June, five; July, none; August, two; September, two.

Immediately after the occurrence of some, if not all, of the seizures, there was greater or less mental lethargy or confusion. The aphonia on one or two occasions, was complete. The ataxia usually increased while the general motor power decreased. The symptoms gradually lessened in intensity up to the date of the next attack; so that the patient had periods of great physical and nervous disturbance, alternating with periods in which the symptoms were much less pronounced. Her convulsions were not minutely noted, but they coincided with the description of none which follow a well-defined course. In one which I had a chance to observe she called out that she was dying, then, with her eyes rolled toward the ceiling, she was seized with a violent general convulsion.

It was the opinion of the writer at this time that she had many symptoms of hysteria—superadded to those resulting from some obscure, ill-defined organic trouble, probably a gross brain lesion.

On November 18, 1888, at five o'clock in the morning, the night nurse discovered that the patient was breathing very heavily and was unconscious, and at once notified me. The pulse was slow, full and strong (about 65); breathing stertorous; cheeks puffing out with each expiration, but regular in rhythm. The head and mouth were slightly drawn to the left side; pupils small, equal, and both responsive to stimulus of light. Tickling the soles of the feet and palms of the hands failed to produce any reflex action. Four drops of croton oil, with a little whiskey, were placed upon the tongue. An ice-cap was applied to the head, which was elevated. The oil failed to operate. The patient died at 8.50 A.M., the same day.

Autopsy.—26 hours after death. Rigor mortis well marked.

Brain-Envelopes.—On removing the calvarium, the dura mater which was presented to view was of a dark blue tinge in the lower or posterior half, the color being most marked along the longitudinal sinus. Upon cutting through the dura, this coloration was found to be due to a large amount of extravasated blood, partly clotted, between the brain proper and the membranes; but the pia mater and arachnoid were perforated at one point, so that the blood was directly beneath the dura. The convolutions of the brain were well marked, the sulci unusually deep, but the layer of gray matter rather thin. The vessels of the pia mater were somewhat engorged.

Cerebellum, left side.—Upon section, a cavity somewhat larger than a walnut was discovered, occupying the centre of the lobe. The walls of the cavity were quite ragged and at many points there were adherent to them small clots. These were mostly grayish or yellowish-white in color, and seemed to be well organized. At three or four points small fibrous bands (old blood-vessels) were joined to the clots from the cavity wall. The principal portion of the cavity, however, was occupied by a single, large, dark-red clot, apparently of recent origin. There was direct communication between the blood in this cavity and that upon the outside, already referred to, by means of a small ragged laceration in the gray matter of the cerebellum, which formed the posterior wall of the cavity.

Cerebrum, right side.—In the bottom of the sulcus between the first and second convolution, and midway between the anterior and posterior extremities of the frontal lobe, was a well organized, reddish-brown clot, of the size of a pea. It principally occupied the gray matter. In the centre of the Island of Reil, just beneath the gray matter, and occupying the greater portion of the island, was a large reddish-brown, or rusty colored, clot. Midway between the anterior and posterior boundaries of the parietal lobe, near the great longitudinal fissure, was a clot the size of a pea. It was situated partly in the gray and partly in the white matter, and was grayish-white in color.

Cerebrum, left side.—In the lower extremity of the ascending frontal convolution, a small reddish brown clot was found of the size of a pea. In the ascending frontal convolution, near the longitudinal fissure, was another small clot, well organized. In the occipital lobe, near the junction of the parieto-occipital and longitudinal fissures, on the outer aspect of the brain, a rusty-brown, moderately firm clot about size of a shellbark was found.

Base of brain.—The vessels were atheromatous in numerous places, this condition being especially marked in the middle cerebrals. It was thought that some of the immense cerebellar hemorrhage found its way into the fourth ventricle, although no means of communication between the two cavities could be demonstrated.

The principal points of interest in this case are as follows:

1. The immense cavity in the cerebellum, with the contained clot.

2. The large number of old clots on the cerebrum.

3. The obscurity and complexity of the symptoms which the case presented.

4. The fact that such extensive destruction of brain matter was compatible with life.

5. The possible confirmation of a theory, to be mentioned hereafter.

Almost all the white matter and the included "*arbor vitæ*" of the left cerebellum was disintegrated. Evidently some morbid process had been active here for a long time prior to the death of the patient. Most likely hemorrhages had occurred here from time to time. Clots were formed. These broke down into pus and were re-absorbed; but the process of disintegration had also involved brain substance. Hence the large extent of the cavity. This process of retrograde metamorphosis also involved the blood-vessels in this region. The large clot which was found in the cavity was evidently of recent origin and due to the rupture of a vessel of considerable size. This hemorrhage, with the pressure which it caused in this region—and most likely too in the floor of the fourth ventricle—was doubtless the immediate cause of death.

Some of the "attacks" which occurred at irregular intervals since 1886, were doubtless symptoms resulting from cerebral hemorrhage, while others were "motor explosions" or "pressure symptoms." It is not unlikely that several of them were principally or wholly of an hysterical character. It is interesting to note that the almost entire destruction of the function of one side of the cerebellum produced no train of characteristic symptoms, or symptoms by means of which the condition could have been diagnosticated.

That such extensive destruction of white and gray matter should produce as few disturbances as it did seems to me to be an argument in favor of the theory which Brown-Séquard recently advanced, that there are, for many, and perhaps all brain centres, supplemental centres. If the main or primary centre be destroyed the secondary or auxiliary centre is capable of taking upon itself a good portion of the work of the primary centre, and the extra work thrown upon the secondary centre tends to develop its capacity and power: just as we see unusual or compensatory development of a leg or arm when its fellow has been removed. At least this seems to me a very plausible theory by which to account for the gradual disappearing and recurrence of the aphasia from time to time in the case just described, when at the autopsy an almost entire destruction of the speech centre (lower part of left ascending frontal convolution) was noted.

The gradual lessening of the ataxia, the temporary increase in the muscular power, and the decrease and subsequent increase of the power of volition, would all seem to point to a confirmation of the theory.

—The *Lancet*, Feb. 16, says that the Queen of England has granted permission to those ladies in whose case illness, infirmity, or advancing years have rendered the usual costume unadvisable, to appear at the Queen's Winter Drawing-room in a high court dress. The term "high," unfortunately, is only a relative one, as the dress still leaves the front of the chest partly exposed.

THE TREATMENT OF SPINAL CARIES.

BY JAMES K. YOUNG, M.D.,
PHILADELPHIA.
INSTRUCTOR IN ORTHOPÆDIC SURGERY, UNIVERSITY OF PENNSYLVANIA; ATTENDING ORTHOPÆDIC SURGEON, OUT-PATIENT DEPARTMENT, UNIVERSITY HOSPITAL.

The treatment of spinal caries may be divided into constitutional and local. The former includes the improvement of the general health and hygienic surroundings, a generous diet, with the exhibition of tonics and alteratives, such as syrupus ferri iodidi, lactophosphate of lime, cod liver oil, hypophosphites of lime and soda, with strychnia, etc. Recumbency is to be enjoined during the acute stage, with or without extension. In very young children the "*stehbett*," of Phelps,[1] or an ordinary fracture-box containing a pillow, will fulfil all the indications. If these become intolerable, after the accurate application of a spine-brace, the child if old enough should be encouraged to walk with assistance or be allowed to go about on all-fours after the plan of the Alaska Indians, who doubtless have copied it from the lower animals, in whom we are told vertebral caries does not occur. Davy[2] suggests that caries "is possibly one of the penalties we pay for walking in the upright position," while Albrecht[3] assumes that the upright position is the chief cause.

The local treatment is divided into mechanical and surgical. Local applications—such as counter irritation, heat, cold, etc.—are of greatest service where secondary lesions of the nervous system exist.

If the cases are diagnosticated early, their cure can be effected without deformity and with perfect flexibility, but as deformity has, in the majority of cases, occurred before the surgeon is consulted, all that can be accomplished by mechanical treatment is the fulfilment of the three indications:

1. To support the diseased spine.
2. To remove superincumbent weight.
3. To prevent increase of deformity.

The machines and appliances for the treatment of caries of the spine are innumerable, but they can all be classed in two groups: (a) the fixed jacket, of plaster of Paris and its modifications in silicate of soda,[1] poro-plastic felt,[2] leather,[3] woven-wire,[4] paper,[5] bamboo,[6] etc.; and (b) the spine-brace. The plaster-of-Paris jacket filled a long-felt want, and too much cannot be said in praise of the illustrious surgeon who popularized this useful appliance. The spine-brace of Dr. Taylor—the antero-posterior leverage spinal apparatus—has in my hands proved more satisfactory to the patient, has certain advantages which the other does not possess, and admits of frequent readjustment. For all cases of disease above the mid-dorsal region (6th dorsal vertebra) a chin-rest should be used to remove the weight of the head and neck.

The brace should always be applied with the patient lying prone on his face, in which position the spine is straightened out as much above and below the seat of deformity as if the patient were suspended. It is now recognized that the deformity itself cannot be straightened. In fact, attempts to accomplish this have been followed by immediate paraplegia and even death.[7]

The surgical treatment of spinal caries is yet in its infancy. It has been the habit of surgeons to treat the abscesses expectantly, to allow them to open spontaneously, to aspirate, or incise, and then allow them to close. These methods in many cases did well, but of late there is a growing tendency to do something in an operative way. Evacuation and hyperdistention of the cavity[8] with various antiseptic fluids has been much practised (Wood, Israel, Agnew, Treves, Dollinger and others) but the operation has not fulfilled what was anticipated from it, and Demours and Demoulin[9] have recorded a death from it.

Under strict antiseptic precautions openings and counter openings with insertion of drainage tubes have been tried, and some surgeons have freely laid the abscess cavities open, and thoroughly curetted the walls.

Dr. Rupprecht, of Dresden, who four years ago was an ardent advocate of this

heroic plan of treatment, informed me last summer that about one-half of the patients subjected to the treatment died of tuberculosis, the other half recovered, and that he had abandoned it. This is not as favorable as the experience at Volkmann's klinik,[1] where 20 patients died of tuberculosis subsequently, and in 23 the abscesses healed.

At present there is a desire on the part of surgeons to treat abscesses and sequestra of spinal caries just as in other parts.[2] Dr. H. L. Taylor,[3] of Cincinnati, has shown anatomically that "the bodies of all the vertebræ are accessible to the surgeon," and "that there is little danger of opening the pleural cavity"; and Dr. Thomas Lafflin suggested about the same time before the Royal Academy of Medicine in Ireland that this operation (sequestrotomy) should be extended to all the dorsal vertebræ. Doubtless these advances are all in the right direction and promise much, but it has occurred to me that the rule should be observed to operate in hospital cases where the disease is progressing in spite of appropriate treatment, but to avoid operation as long as possible in private practice, because in the latter patients are more apt to recover without operation.

The most common complication (aside from abscess) is paraplegia, and it is encouraging to know that so many recover from this distressing symptom. Taylor and Lovett[4] report out of 19 cases that 17 patients recovered; 1 recovered partly, and 1 remained paralyzed. Of 38 cases reported by Sayre either partly or completely paralyzed, 34 patients have recovered and 4 remain under treatment. The treatment consists in the application of a spinal support and in placing the patient in a recumbent position, with in some cases the administration of large doses of iodide of potassium, as suggested by Gibney.[5] These are tolerated even by children to a remarkable degree, but Ridlon[6] declares that "he (had used iodide of potassium and) had been convinced that it produced no effect upon the paralyzed unless there be reason to believe that hereditary syphilis is present"; and this has been my experience also.

Society Reports.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, March 25, 1889.

The President, Alexander S. Hunter, M.D., in the chair.

Dr. August Seibert read a paper on

The Etiology of Fibrinous Pneumonia.

Formerly pneumonia was regarded as due directly to cold. Only within the last twenty years, after the attention of medical men had been drawn to repeated observations of endemics and epidemics of pneumonia, and since the pathological changes during other processes could be traced to the division and growth of infectious material brought into the human body, and since the old ideas on inflammation and the formation of pus were modified by antisepsis, have prominent observers come forth with the theory that fibrinous pneumonia is an infectious disease. It was found by Leube, in 1877, that all the symptoms except the elevation of temperature were present in some cases; this certainly did not coincide with the prevalent idea regarding active inflammation. Gradually statistical reports concerning soldiers in the field and in barracks, Arctic expeditions, convents, boarding-schools, etc., were prepared, which went to show that persons leading an out-of-door life, often exposed to bad weather, were in less danger of pneumonia than those who lived indoors. They also showed that the tendency to get pneumonia was in exact proportion to the time spent in closed rooms.

Dr. Seibert cited numerous statistics of epidemics or endemics of pneumonia among persons confined in rooms which were warm, moist, and filthy. It was only natural that these manifold reports, mostly dated within the last twenty years, should stimulate some to experiments, others to statistical comparisons. Haidenhain attempted to produce pneumonia by forcing cold air into the lungs of animals, and failed; and others failed after him. A number tried to find the peculiar weather influence present in determining the frequency of pneumonia, and failed; but Poet, Seitz, Baker, and Seibert were more successful, and their results coincided very much, though differing in explanation.

In his first report on an investigation regarding pneumonia and the weather, published in the *American Journal of Med. Sciences*, in 1882, Dr. Seibert was able to prove that catarrh of the air passages and pneumonia showed similar lines of frequency. This view has since come to be generally admitted. In a collective investigation regarding pneumonia and the weather carried on by the Committee on Hygiene of the New York County Medical Society, in 1884–5, 44 practitioners of New York and Brooklyn and four hospitals took part, and gave the following results: 1. The origination of fibrinous pneumonia is greatly favored by certain meteorological conditions, thus explaining the difference in its frequency during the twelve months of the year. 2. Low and falling temperature, high and rising humidity, and high winds are each capable alone of exercising this influence. 3. If two of these weather conditions are found together there are more cases of pneumonia than when one is found alone. 4. If the three (cold, moisture, and high winds) are present, the frequency of pneumonia is great. Existing catarrh predisposes to fibrinous pneumonia.

In all his cases of endocarditis complicating pneumonia, Weichselbaum was able to cultivate Friedländer's pneumococcus from the pathological deposits on the endocardium. Emil Senger also found this organism, in all fatal cases of pneumonia, in the lungs as well as in organs involved in the complications, in cases of meningitis, pleurisy, endocarditis, nephritis and pericarditis.

On reading the article of Dr. Sternberg, in the *Medical Record*, March 16 and 23, Dr. Seibert was satisfied that Fraenkel's coccus, described by Dr. Sternberg as "micrococcus Pasteuri," would probably cause the more frequent form of pneumonia, known as the sthenic variety, while the pneumococcus of Friedländer was the usual agent for producing the asthenic, bilious, or typhoid variety. But to his mind the most important investigations regarding the germ origin of pneumonia are those of Rudolph Emmerich. In the State prison at Amber, where an endemic of pneumonia had attacked 161 and killed 46 out of a total of 1150 prisoners, Emmerich found Friedländer's coccus between the ceilings and below the floors of the sleeping apartments in great quantities, imbedded in very moist *débris* which had been used to fill up the spaces. White mice infected by injections of the coccus into the lung-tissue all died, and artificial pneumonia also occurred in some when they inhaled the microbe.

Secondary infiltrations in wandering pneumonia are to be explained, not by inflammation passing by continuity of surface, but by the presence of an infectious material. Central pneumonia, and cases lasting but one or two days, also favor the infection theory. Endemics and epidemics prove not alone that pneumonia is caused by specific poisons, but also that the germs are apt to thrive and grow in certain localities at certain times and under certain conditions. Whether or not pneumonia is contagious, so that the germ of the disease may pass directly from the patient to the attendant, as in diphtheria and scarlatina, has not yet been settled. It certainly is, if at all, contagious only to a very mild degree. Friedländer's pneumococcus appears to thrive best in warm, moist, dirty rooms and houses. This statement accords with observed epidemics.

Pneumonia is found oftener in old and very young persons than in the middle aged. Children under two years of age are attacked oftener than older ones; the explanation being that old people and children spend more time indoors.

Pneumonia not only frequently attacks persons suffering from bronchial affections, but it is also found complicating those diseases in which the pulmonary mucous membrane is usually in a state of congestion and hyperæmia, as in typhoid fever, measles, and pertussis. On the other hand, it is not often seen complicating scarlatina, diphtheria and meningitis. We are forced to conclude that the catarrh of the bronchi being absent in the one class of diseases, the opening in the mucous membrane necessary for the admission of the pneumococcus poison is wanting.

In conclusion, he said: fibrinous pneumonia is an infectious local disease, showing more or less general symptoms, the origination of which is greatly favored by existing bronchial catarrh, poor ventilation of rooms, moist and filthy condition of houses, and cold, moist weather.

Dr. Francis Delafield opened the discussion, and stated that there is no other department of medicine in which so little advance has been made as with regard to the causation of disease. What advance has been made, however, is due to physicians no longer accepting general statements as to causation, but requiring more and more exact data. There is much yet to be learned with regard to the etiology of

pneumonia. It is known only in a general way that pneumonia seems to belong to the class of infectious inflammations, that is, inflammations in which the inflammatory process is always accompanied with the production and growth of pathogenic bacteria. Such inflammations require for their causation three factors, any one of which in different instances may take the prominent part, namely: (1) a pathogenic bacterium; (2) some other exciting cause of the inflammation; and (3) individual susceptibility. With regard to the pathogenic bacteria, all we knew is that it seems pretty evident more than one form of bacteria is capable of causing the inflammation of the lung.

Dr. L. E. Holt has been impressed with the varying degrees of susceptibility of different patients to fibrinous pneumonia. He has found this form of pneumonia more common during the third, fourth, and fifth years, than before the second. As to its presence in measles, he has never seen it at a *post-mortem* on a patient dead of measles complicated with pneumonia; the pneumonia has always been of another form.

The discussion was continued by Drs. A. F. Currier, Messenger, and the author.

Reports of Clinics.

COLLEGE OF PHYSICIANS AND SURGEONS—VANDERBILT CLINIC.

MEDICAL CLINIC—PROF. DELAFIELD.

Cardiac Hypertrophy, Dilatation, etc.

The first patient was a woman, 48 years old, who gave following history: she had "malaria" six years ago; fourteen months ago she had pneumonia on the right side, and was in bed for two months, and then began to improve slowly, and was in fair health during the succeeding summer. Last fall, she suffered from cough, and once expectorated a little blood; with this she had anorexia and vomiting, and was extremely prostrated. About this time, on October 29, she was examined at the Clinic. The urine was found to be normal. The heart extended from the right edge of the sternum to the anterior axillary line; the apex was in the sixth inter-space; there was a presystolic thrill; and presystolic and systolic murmurs were heard at the apex. The patient was given chloral hydrate and nitroglycerin, and was put upon fluid diet. She improved. On November 14, the treatment was changed to iodide of potash and strophanthus, after which improvement was so marked that the patient has remained away until now. She says that since one week she has had a return of her cough and dyspnœa. She is so feeble as to be scarcely able to be about, vomits after eating, and is unable to retain anything on her stomach, and is suffering from general pains throughout the body.

On examination the urine is found to have a sp. gr. of 1,013, and shows a trace of albumin. The patient's temperature is 98.8°; the skin is moist, the pulse quick and very feeble. The heart's area is as before noted: there are both hypertrophy and dilatation; its impulse is more forcible than that of the pulse—it is a laboring heart. No murmur can be detected now, but since it was observed at a previous examination, there exists probably mitral stenosis. Such a murmur is often missing. The case is, therefore, one of old mitral stenosis, with secondary hypertrophy and dilatation of both ventricles and a disposition of the heart to take on rapid and irregular action. This is the second occasion on which this has taken place. The cardiac condition present in this case may occur apart from mitral stenosis, and mitral stenosis can exist and the heart act perfectly well; or, again, they may occur together, as in the present case. As a matter of fact, in these cases, we often have a laboring heart and a feeble pulse.

With regard to treatment, ordinary drugs do not aid much. The arteries are already dilated, so that decreasing the tension will not strengthen the pulse. And the heart is working harder than it should, and yet does not fill the arteries, so that digitalis, convallaria, strophanthus, etc., are harmful, as a rule, though we sometimes find that under the influence of these cardiac stimulants the heart will not labor so much. Yet it is not safe to try them experimentally. They are liable to make the patient worse if not given at the proper time.

Dr. Delafield recommended, first, complete rest in bed, not allowing the patient even to sit up. This alone, he said, does wonders in some instances.

There is one drug which may be of benefit, but whose exact scope is not as yet fully defined, viz., the chloride of barium, given in teaspoonful doses of a one per cent. solution three times daily.

Dr. Delafield had showed to the class a case similar to this one, a short time ago, at the Roosevelt Hospital, in which the heart's

action was even more marked. Here, rest alone gave no improvement. Then the chloride of barium was used, and in two days marked benefit in every respect resulted. In some cases, he said, barium chloride will do no good.

The most reliable treatment is by absolute rest. This patient might fall dead at any moment; she is not safe while walking about. Even under treatment she may not improve.

Chronic Alcoholism.

The second patient was a man, 45 years old, a hard drinker. Two years ago he had pains across the stomach and loins, and "lightness of the head," and says he had an attack of unconsciousness lasting two weeks. He has had since several similar attacks, but they have been less severe. Three months ago he began to complain of dyspnœa and palpitation, with some œdema of the ankles, and he suffered with morning vomiting and flatulence, and swelling of the abdomen. An examination now shows that at present the urine is of a sp. gr. of 1,013, and has a trace of albumin. The radial pulse is very small—is felt with difficulty; in the temporal artery it is very feeble and quick. The pulmonary resonance all over the chest is of short duration, high pitch, and altered quality; expiration is prolonged, especially on the right side (emphysema). The apex beat of the heart to the left of the nipple is increased in area. The apex can be felt, but the impulse is not forcible; it gives evidence of considerable dilatation. The heart's action is feeble and irregular; there is no murmur. The left and right sides of the heart are both enlarged.

The liver is somewhat diminished in size. The spleen is not enlarged.

The diagnosis is in the first place chronic alcoholism. This has developed several conditions, namely, chronic gastritis, cirrhosis of the liver (without jaundice), atrophied kidney, emphysema (without bronchitis) and dilatation of both ventricles of the heart (probably secondary to the emphysema). This dilatation is apt to occur with emphysema and intemperance, especially in beer drinkers.

This man is well nourished and in a tolerably fair condition. He would not be suspected of having valvular disease, whereas the previous patient would be. Why? Because—leaving the duration of the disease out of the question—of the character of the heart sounds. In this case they are good and clear cut, though not so strong as they are normally. In the other, the reverse is true. The treatment here will be unsatisfactory because the patient will continue to drink.

Dr. Delafield recommended digitalis in moderate doses, kept up for a considerable length of time.

Chronic Constipation.

The third patient was also a man, 35 years old, a tailor. He was shown to the class four weeks ago, when he was complaining of feebleness, loss of strength and flesh, pains in the abdomen, and long continued and persistent constipation. The patient was then unable to do his work. The diagnosis of constipation was made, and it was believed no organic disease was present. The patient was admitted to Roosevelt Hospital and placed upon as liberal a diet as the Hospital afforded. He was given the following pill:

℞ Strychniæ sulphatis . . . . gr. 1-40
Pulv. ipecac.,
Ext. belladonnæ,
Ext. colocynthidis co. . . . āā gr. ¼
M.

At first he took four daily, then three, and then two. At once his constipation was relieved.

He is about to leave the Hospital and resume his work. At present, his appetite is good, he has no pain, and has gained and is still gaining strength and flesh.

He should continue with his pills, taking now one a day, and after a while they may be stopped and diet made to supply their office.

Some cases of this kind, Dr. Delafield remarked, are easily managed; others are not.

Pleurisy with Effusion.

The next patient was a man, 40 years old, a laborer. Up to four days ago was able to work. Then pains in the stomach, diarrhœa and vomiting set in. He now complains of neither cough nor dyspnœa nor pain in the chest. To-day his temperature is found to be $103\frac{1}{5}°$; his pulse 140. The urine has a sp. gr. of 1,022, and contains considerable albumin. An examination of the chest shows dulness over the lower lobe of the right lung, and an absence of breathing and voice sounds.

The diagnosis rests between acute lobar pneumonia and pleurisy with effusion, being in favor of the latter from the patient's general condition; and yet from the data so far obtained it is impossible to decide posi-

tively. To be certain of the diagnosis we may either wait a day or so, when the signs will further develop, or we may use a hypodermatic needle.

The patient is exhibited to illustrate two points: first, the vague subjective symptoms of the pulmonary trouble, and second, the impossibility of differentiating in every case between these two diseases at a certain stage, relying alone on the physical signs.

Subacute Diffuse Nephritis.

The last patient was a man, 35 years old. Two or three years ago he had an attack of sickness, confining him to bed. He suffered, at that time, from pains and swelling in the hands, feet, and less generally throughout the body. After a while the swelling subsided, the patient improved, and he was able to leave the house in two months. Since this time there has been occasionally some swelling of the ankles; he has complained of headache, insomnia, and constipation. His appetite is fair and there has been no vomiting, and he is able to work.

On examination the urine is found to have a sp. gr. of 1,016, and to contain a large quantity of albumin. The pulse is good. Arterial tension slightly increased. The heart is normal in size, with no adventitious sounds.

The history is a straight one of subacute diffuse nephritis, beginning about three years ago. There has been no sharp attack since the first one, though the amount of albumin in the urine has varied probably in different weeks and months. The changes at first produced in the kidneys have remained—and even increased. The inflammation is both exudative and productive, more and more connective tissue has been formed, and the glomeruli have also undergone change and are less able to do their work. Hence the low specific gravity of the urine. We would find also that the urea excreted is less in quantity than it should be. The exudative part of the inflammatory process will probably lessen little by little, and finally stop; but the productive part will go on increasing more and more, perhaps not advancing much for many years to come, but certain to advance sooner or later. Sometimes these cases remain stationary for many years.

—The Hahnemann Medical College held its forty-first Annual Commencement April 4, and conferred the degree of Doctor of Medicine on 65 graduates.

PERISCOPE.

Nature and Prevention of Urethral Fever.

Dr. James Bell, Surgeon to the Montreal General Hospital, in a paper read before the Medico-Chirurgical Society of Montreal, says that all surgeons, and in fact most general practitioners, are familiar with certain forms of constitutional disturbance which follow instrumental or operative interference within the urethra. In a certain number of such cases pre-existing disease of the kidneys, ureters or bladder, or of all these organs combined, or the setting up of a true sepsis (pyæmia or septicæmia), or the production of the disease known as surgical kidney, may explain these symptoms. But there still remains a large class of cases occurring in male patients of all ages, and often where no lesion of any organ can be discovered, even by post-mortem examination, in which instrumental or operative interference within the urethra is followed by the train of symptoms to which has been given the names urethral fever, urine fever, catheter fever, etc. These symptoms, he says, occur in one of four different forms: 1. Shock, collapse and death within a few hours after operation (9 to 24), with or without chill or fever, and with partial or complete suppression of urine. 2. A severe chill with high fever occurring a few hours after operation, and usually following the first act of micturition. Profuse sweating and prostration follow, but the whole disturbance lasts only from a few hours to two or three days. 3. Recurrent chills and high fever coming on at irregular intervals and lasting perhaps for weeks or months. 4. A moderate fever with slight chills or chilly feelings accompanied with great depression, low muttering delirium or semi-coma, dry, cracked tongue and anorexia, and usually ending fatally. Such cases occur only in old men with enlarged prostates, and in whom, as a general rule, attempts at catheterization with solid instruments have resulted in the formation of false passages just in front of the prostate and on the floor of the urethra. This form differs materially from the preceding ones, but clinical experience points strongly to its being identical in its origin.

Patients belonging to the second and third classes, he says, generally recover completely and satisfactorily. He then refers to three distinct theories which have been advanced as to its origin: (1) That it is a septic process; (2) that it is due in

some obscure way to reflex nervous phenomena; (3) that it is due to uræmia.

After declaring these theories inadequate to explain the affection, he states that the discovery of the animal alkaloids known as ptomaines and leucomaines, and the experiments of Dr. Bouchard of Paris from 1882 to 1886 upon the toxicity of the alkaloidal substances found in normal urine seem to have given the key to a rational explanation of the origin of urine fever. From the amount of evidence which we now possess Dr. Bell thinks there can hardly be any doubt that this disease is due to the absorption of the products of decomposed or decomposing urine from cut, lacerated or abraded portions of the urethra. It is not a septic process, but a form of poisoning closely allied to uræmia and due to the absorption of a toxic alkaloid produced by or during the decomposition of the urine. The clinical facts pointing to this conclusion, he says, amount almost to a demonstration. They are as follows: 1. Urine fever is unknown after perineal lithotomy, external urethrotomy and internal urethrotomy in the pendulous urethra, and is far less frequent when the urethra is wounded on its roof than when it is wounded on the floor. 2. When, after internal urethrotomy, the urethra and bladder have been carefully washed out with an antiseptic solution, urine fever does not occur until some time after urine has been passed over the wounded urethral surface, and is then of a mild type and generally free from danger. 3. Operations upon the female genitals which wound or injure the urethra are not followed by any similar condition. 4. Mr. Harrison of Liverpool has shown by a number of operations that when the bladder is drained by a perineal wound after internal urethrotomy that urine fever never occurs, and he attributes its origin to the absorption of the products of decomposing urine from wounds of the mucous membrane.

Dr. Bell then contributes his experience in support of this important observation and adds his testimony in favor of the combined operation. He has records of five cases in which he has performed, within the past twelve months, the combined operation, and also of six cases of simple internal urethrotomy for stricture of the deep urethra performed within the same period of time. The five cases in which he drained the bladder by a perineal cystotomy were selected for this operation because of specially bad features in each case. The six cases in which he did a simple internal urethrotomy were, with one exception, not drained, because they were more favorable cases for operation. In the first series, in which he drained through the perineum, there was not in any case a subsequent rigor or rise of temperature, while in the six cases of the second series urine fever in a mild form followed in four cases, but only after micturition. Only two cases escaped, and in these he believes the result was due in great part to greater intelligence on the part of the patient in carrying out instructions.

After giving brief account of each of the cases referred to, he submits the following conclusions:

1. That urine fever is a consequence of the lodgment and decomposition of urine in contact with wounded urethral surfaces, the inference being that the absorption of the product of decomposition which takes place from the wounded surfaces, and which could not occur through the normal urethral mucous membrane, is the direct cause of this condition. Mr. Harrison has also shown that patients whose urine contains a diminished quantity of urea are less liable to urine fever after operations upon the urethra.

2. Urine fever is *absolutely preventable*, either by preventing the decomposition of the urine in contact with urethral wounds, or by providing a dependent drain so that it cannot lie in contact with wounded urethral surfaces long enough to decompose.

3. That a perineal cystotomy is a simple and easily performed operation, which does not materially add to the risks attending urethrotomy, and is not followed by unpleasant results if the drainage-tube or catheter be not too long retained in the perineal wound.

4. That decomposition of urine can be delayed for a considerable time by thorough cleansing of the urethra and bladder by injection of a weak antiseptic solution (salicylic acid or sublimate) after operation. This, with the precaution on the part of the patient of abstaining from passing urine for as long a time as possible, will greatly lessen the frequency of occurrence of urethral fever and diminish its risks. Repeated washings of the urethra in this way after each act of micturition for a few days would probably prevent the attack of fever altogether.

5. Quinine, aconite and other drugs may be of use when urine fever has occurred, but they are powerless in most cases to avert it.

6. Patients with enlarged prostate whose deep urethras have been lacerated by the passage of solid instruments should be

treated by perineal cystotomy at once in order to arrest urine fever (or sepsis), either of which is likely to occur as soon as the patient is able to evacuate a part of his urine without the catheter.—*Montreal Medical Journal*, Feb., 1889.

New Procedure in Anticipated Complete Rupture of the Perineum.

At the meeting of the Chicago Gynecological Society, Nov. 16, 1888, Dr. Edward B. Weston read a paper, entitled A New Procedure in Cases of Anticipated Complete Rupture of the Perineum, in which he said that on the fourth day of last October he was, for the fourth time, called to attend Mrs. H. in labor. The patient was a woman somewhat below the average size, and had rather a narrow pelvis, while her children were all large at birth. At the birth of her first child, a boy who weighed twelve pounds, a complete laceration of the perineum was received. The second child, also a boy, weighed nine and one-half pounds, and the perineum was torn to the anal sphincter. The third pregnancy was terminated in the sixth month by unknown cause. The child was of course small, but delivery took place very rapidly, and there was again a rupture, though not to the same degree as in the second labor. On visiting the patient at the beginning of her last labor, an examination showed a well-restored perineum, and a child seemingly very large, presenting in the first position.

On meditating over the situation, remembering what had taken place in her previous labors, Dr. Weston feared a complete rupture would again occur, however well he might apply the various methods or procedures for protecting the perineum. The thought came to him that it would be well to introduce a deep suture before the laceration occurred, and before the head began to press upon the perineum, so that if complete rupture did take place he would have one suture already in place, by means of which he could easily bring the parts into accurate apposition, and which could, in a measure, be used as forceps or tenaculum, and be of great service in whatever after-operation might be necessary. He therefore with a long curved needle introduced a silk suture a little more than half an inch to the right of the anus, and carried it up about an inch and a half in the recto-vaginal septum, and brought it out on the left side at a point corresponding to its point of entrance. Each end was left six inches long and then tied together. Again there was a laceration, though not a complete one. The child, a boy, weighed eleven pounds.

In the discussion that followed the reading of the paper most of the speakers agreed that the procedure instituted by Dr. Weston was a proper and valuable one as simplifying the primary operation for rupture of the perineum.—*Am. Jour. of Obstet.*, Feb., 1889.

Toxic Action of Edible Mushrooms.

It is generally supposed that edible mushrooms are under all circumstances a safe article of diet, but some recent observations made in Switzerland appear to show that there may be danger in at least one species, if it is preserved in the dry state. Some persons in Berne who had eaten a quantity of the mushroom known as Helvella (or Morchella) esculenta, which had been purchased in the dry state, were seized with abdominal pain and vomiting a few hours afterward. It was at first thought that some poisonous species must have got mixed with the Morchella esculenta, but upon examination this was found not to be the case. A decoction of the dried plant was then examined by Professor Demme, with the result that it evidently contained a powerful poison, the behavior of which, when tested on cold-blooded animals, produced the impression that it was much more nearly allied to curare than to muscarin: the residue, when examined, was found to be inert. The toxic substance, whatever it was, appeared to have no connection with the Helvellic acid discovered by Boehm and Külz in Helvella. Trimethylamine was prepared from a watery distillate of the dried mushroom, and the watery and alcoholic infusions contained a base which presented all the chemical and poisonous characters of neurin; the presence of other basic bodies also belonging to the group of ptomaines was suspected. The theory suggested by Professor Demme and Dr. Berlinerblau, who was associated with him in the investigation, is that the highly nitrogenous mushroom substance is capable, under special circumstances, of undergoing certain putrefactive changes which lead to the formation of products of a poisonous character bearing a close analogy to those formed during the putrefaction of animal bodies. Consequently there is a double source of danger in eating mushroom—viz., the chance of admixture of poisonous species and the possibility of the existence of ptomaine-like bodies arising from partial decomposition having set in.—*Lancet*, March 2, 1889.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium, - - - -	**6.00**

P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

PHYSICIANS AND PROHIBITION.

At the present time the readers of the REPORTER in at least three States are no doubt thinking very seriously in regard to the attitude which they will assume or maintain in regard to the proposed amendments to their State Constitutions prohibiting the manufacture and sale of alcoholic liquors for drinking purposes.

Physicians know, perhaps better than any class in the community, the physical dangers of the improper use of alcoholic drinks and the risks involved in even a moderate use of them; yet, while some physicians are bitterly and unreservedly opposed to the use of alcoholic liquors, even as drugs, we think the great mass of medical men are disposed to consider the relative claims of temperance and total abstinence without prejudice, and without any of the absurd and untenable assumptions which furnish the stock in trade of many well-meaning but illogical moralists. Facts, we believe, appeal to our professional brethren, and facts will determine what they shall think and say in regard to the proposal to prohibit the sale of alcoholic beverages in Massachusetts, Pennsylvania and Nebraska, and in any other States in which the matter shall hereafter come up.

This being the case we cannot do better than to consider how prohibition has worked in States where it has been in force for some time.

The three most conspicuous examples of the results of prohibition are Maine, Kansas and Iowa. After thirty-six years of thorough testing, the verdict of the vast majority of the citizens of Maine is unqualifiedly favorable to prohibition. Every declaration of opinion that comes from responsible sources, every deliverance on the subject in the public press, on the political platform, or from the lips or pens of those qualified to judge, affirms the benefit and effectiveness of prohibition. Official records verify the statement that, before the enactment of this law, distilleries, breweries and saloons were in operation day and night throughout the State. To-day, although drinking is not wholly abolished, not a distillery, brewery or open saloon is plying its vocation within the borders of that State.

In 1884 Iowa placed on her statute books a stringent prohibitory liquor law. At the time of its enactment the liquor traffic held undisputed possession of the field. Distilleries, breweries and saloons were conducting their business openly in every part of the State, and no successful effort had been made to restrict or restrain them. At the end of four years, Governor Larrabee, himself an opposer of prohibitory legislation

when first proposed, declared that in eighty-five of the ninety-nine counties of the State the law is absolutely effective, and in the remaining fourteen partially enforced, with a steady advance toward complete enforcement. More than half of the county jails are vacant; pauperism and crime are steadily decreasing; intelligence and morality are advancing; the resources of the State are rapidly developing, and prosperity is said to follow every department of trade and every branch of industry.

The effect of prohibition in Kansas is indicated in a recent article in the *Topeka* (Kansas) *Capital Commonwealth*, replying to questions in regard to the effect of the prohibitory liquor-law in that State and the sentiment of the citizens in regard to it. From this article we learn that drunkenness and crime have diminished eighty per cent. since the saloons were closed in Kansas; that pauperism has decreased very materially, while the welfare of the people and the prosperity of the State have improved in equal proportion.

In his farewell address to the Kansas Legislature last January, Governor Martin said that no observing and intelligent citizen has failed to note the beneficial results already attained. Nine-tenths of the drinking and drunkenness prevalent eight years ago has been abolished. Crime has diminished enormously; thousands of homes where vice and want and wretchedness once prevailed are filled with peace, plenty and contentment. Although the population has increased rapidly, the number of criminals in jail has decreased steadily. Many of the jails are empty, and all show a marked falling off in the number of prisoners they contain. In the capital city (Topeka), with 60,000 inhabitants, not a single criminal case was on the docket when the then present term of court began. The business of the police courts had dwindled to one-fourth of its former proportions, and in cities of the second and third class the occupation of the police courts is practically gone.

These facts cannot fail to interest our readers, and must be of service in helping them to shape their expressions and actions intelligently and conscientiously toward the very important question which is before them.

EARLY DIAGNOSIS OF CANCER OF THE CERVIX UTERI.

The relative frequency of cancer of the cervix uteri, the certain death of the patient unless it can be extirpated, and the probability of recurrence unless it is removed early, render the subject of the early diagnosis of this disease one of great practical importance. It has been taught in the past that the cardinal symptoms of cancer of the cervix are hemorrhage, pain, and offensive watery discharge; these symptoms are associated with loss of flesh, debility, and cachexia, and have been considered specially important when they occur in women over forty years of age.

In a short paper in the *Medical Record*, February 9, 1889, Dr. Henry C. Coe considers the value of these symptoms and others as aids to the early diagnosis of cancer of the cervix. Dr. Coe has found that more than one-fifth of the women suffering with this disease are under forty, and that they frequently present every evidence of robust health, even in cases of advanced disease. Pain has been a late symptom, and is often absent. Hemorrhage often has not been sufficient to deserve the name, and very rarely threatens life. Moreover, the foul, watery discharge has not been uniformly present, even when extensive ulceration has existed.

Dr. Coe considers bleeding as the most common symptom noted in connection with incipient epithelioma of the cervix. This may be merely an increase of the menstrual flow — especially in women near the climacteric—but the most significant form of hemorrhage is what the Germans call "atypical," *i. e.*, a slight show at irregular intervals between the periods. It may be

simply a pinkish discharge. This is especially significant when it occurs in women after the climacteric. Bleeding after coitus is always significant, and calls for prompt examination, even if no other symptom is present. A profuse leucorrhœa in a woman who has passed the climacteric should awaken suspicion, even though no odor is detected. Pain, of the severe lancinating character present in the advanced stage, is absent in the early stage. Vague, shooting pains in the pelvis, in women previously free from them, are of suspicious import.

Upon physical examination at this early time the cervix is usually found lacerated, large, thickened, and having peculiar nodules along the edges of the everted lips. At a somewhat later stage, the cervix will feel more like a mushroom. Firm pressure is not painful, but may cause slight hemorrhage. No odor is noted on withdrawing the finger. The uterus is somewhat enlarged, but movable, and there is no evidence of perimetritis. As seen through the speculum, the cervix may present the ordinary appearances seen in erosion — the distinction between which and cancer can often be determined only by microscopic examination. If there is a sharp demarcation between the healthy and the diseased areas, this fact is suspicious. The cancerous nodules appear as glistening yellowish nodules, elevated above the level of the healthy tissue. General hardness of the cervix in connection with extensive erosion is a sinister sign. In order to make a diagnosis in doubtful cases, a section of tissue must be removed and submitted to microscopic examination.

This study of the early diagnostic signs of cancer of the cervix is timely. The practitioner who waits for the appearance of the symptoms heretofore considered necessary to justify a suspicion of the existence of cancer, waits until there is no longer hope of a radical cure by removal of the parts. It behooves us all to study the signs of the invasion of cancer of the cervix, that a vaginal examination may be insisted on, and a diagnosis made while there is yet hope of cure by a radical operation. If we wait for the full development of the classical symptoms our diagnosis is certain, and the doom of our patient is not less certain.

EXCISION OF THE GALL-BLADDER.

The effect of total excision of the gall-bladder has been carefully studied, a few months ago, by Dr. Oddi, who at the suggestion of Dr. Marcacci, removed this receptacle from three large dogs and observed what followed. According to an abstract in the *Centralblatt für Chirurgie*, Feb. 23, 1889, he found in all three cases bile-pigment in the urine, and the stools became liquid, intensely colored and mucous. The animals had an increase of appetite; but they lost flesh. After a month, or a month and a half, these conditions were all reversed. Dr. Oddi thinks that after excision of the gall-bladder bile flows continuously into the intestinal canal, causing a catarrhal condition of the mucous membrane and resorption of the bile-pigments. The wasting he explains on the supposition that smaller quantities of bile meet the chyme as it leaves the stomach, and that therefore its fat is imperfectly emulsified, and consequently less perfectly absorbed. This view seems to be supported by an observation in which he made a fistulous connection between the stomach and the gall-bladder and ligated the ductus communis choledochus. In this case bile-pigments appeared in the urine, but there was no diarrhœa nor loss of weight. On the contrary, the animal had an increase of appetite and gained flesh. This effect Dr. Oddi ascribes to the accumulation of bile in the stomach and its periodical discharge, with the chyme, into the duodenum.

One of the most interesting disclosures of Dr. Oddi's experiments was the fact that removal of the gall-bladder was followed in one case by dilatation of the biliary ducts, while in two of the animals, which were killed after two and three months respect-

ively, the biliary ducts were not much enlarged, while the cystic duct was so dilated that it looked as if Nature were attempting to make a new gall-bladder. Dr. Oddi has already made experiments which lead him to believe that the ductus communis choledochus has a sphincter, and he thinks that after excision of the gall-bladder, the action of this sphincter together with the dilatation of the biliary ducts, may lead to renewal of the normal periodical discharge of bile into the duodenum, and reinstatement of normal conditions of intestinal digestion.

The results of his experiments are of very great interest, and have an important bearing upon the operations which are nowadays practised on the gall-bladder.

TREATMENT OF LOCOMOTOR ATAXIA BY SUSPENSION.

It is interesting to note that Motchoukowsky's method of treating locomotor ataxia by suspension of the patient with bands passing under the chin and occiput and under the arms—the method described in the REPORTER February 23—has been on trial in the nervous clinic of Professors Eulenburg and Mendel, in Berlin. The results obtained by these distinguished specialists in nervous diseases are stated by the *Berliner klin. Wochenschrift*, February 25, 1889, to be in entire agreement with those we have referred to from Charcot's clinic. The patients are at first suspended for one minute, and gradually the time is lengthened until the limit of three minutes is reached, the suspension being practised three times a week. About twenty patients have thus far been subjected to the treatment in the polyclinic in Berlin, and the distrust with which it was first regarded has given way, until now the patients look forward to it with eagerness and steadily growing confidence. Too short a time has elapsed to speak of cures or even of undoubted improvements, nevertheless they say it can be stated that a certain number of patients exhibit after the suspension an easier and freer gait, have less staggering, and complain less of lancinating pains; in a few cases there has been also improvement in the bladder symptoms. Moreover, in their experience up to the present time the treatment has been free from bad symptoms, and is evidently well borne by women.

They are careful, however, to add that the actual value of the treatment is still in doubt, and that physicians should be warned against forming precipitate and exaggerated hopes of it. This last statement obtains support from the experience of the treatment which has been had in the Infirmary for Nervous Diseases in Philadelphia. Fourteen patients have thus far been subjected to the treatment in that institution. As a rule the suspension has been well borne, but care is required to have the pressure equable—not more in the neck than in the armpits. Patients after the suspension is over are found to be unsteady when first let down, so that they are not released for a minute or so. The only unpleasant effect observed occurred in a patient who fainted during suspension, and had convulsive movements; he recovered, however, in a few minutes after being let down. While it is as yet too early to speak of the results obtained at the Infirmary, it is significant that there has not been in any case marked improvement.

MORRELL MACKENZIE AGAIN.—In reply to the notification of the vote of censure passed upon Sir Morell Mackenzie by the Royal College of Physicians, his secretary replied as follows to Sir Henry Pitman, the Registrar of the College:

"SIR: I am requested by Sir Morell Mackenzie to express his surprise that you should have written to him on behalf of the Royal College of Physicians. I am further instructed to inform you that Sir Morell Mackenzie takes no interest whatever in the proceedings or opinions of the College of Physicians, and to request that as the representative of that body you will do him the favor to desist from all further intrusion."

This note is characterized by effrontery which would be surprising in most men, but which is not remarkable in a man who first disgraced his profession, and then in various ways affected indifference to the reprobation his conduct excited.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

HANDBOOK OF THE DIAGNOSIS AND TREATMENT OF SKIN DISEASES. By Arthur Van Harlingen, M.D., Professor of Diseases of the Skin in the Philadelphia Polyclinic and College for Graduates in Medicine, etc. Second edition, enlarged and revised. 8vo, pp. 410. Philadelphia: P. Blakiston, Son & Co., 1889. Price, $2.50.

"Good wine needs no bush," and a book like this one by Dr. Van Harlingen needs little recommendation when it comes to a second edition. It has already secured the approval of the medical profession because it is clear, succinct and interesting. It is admirably adapted to the needs of general practitioners, who are sometimes deterred from the study of dermatology, because the works devoted to it are too ponderous, and filled with elaborate details of which confuse those who are not specialists in this department, and make them despair of gaining a working knowledge of it. Dr. Van Harlingen has brought to the preparation of his book the knowledge gained by many years of faithful study, a large experience as a practitioner and a teacher, and a singularly conscientious method in all that he does.

Those who turn to his book will find it a thoroughly trustworthy manual, and one very convenient to refer to. The various subjects are considered in alphabetical order, so that an index is not needed—and none is given.

We can heartily recommend the book to our readers as one of the most sensible and practical works on diseases of the skin with which we are acquainted.

OBSTETRIC APHORISMS FOR THE USE OF STUDENTS COMMENCING MIDWIFERY PRACTICE. By Joseph Griffiths Swayne, M.D., Consulting Physician Accoucheur to the Bristol General Hospital, and Lecturer on Obstetric Medicine at the Bristol Medical College. Ninth Edition. 16mo., pp. viii, 159. Philadelphia: P. Blakiston, Son & Co., 1888. Price, $1.25.

When a book reaches a ninth edition it is because of its inherent merits, and because it is well adapted to the end for which it is intended. Covering as it does the more practical part of obstetrics, instructing the young practitioner in the details of the conduct of the accoucheur toward his patient, laying down sound methods of treatment for easily managed puerperal cases, and pointing out the cases in which the beginner stands in need of counsel, the "Obstetric Aphorisms" supplies a want on the part of young practitioners which is not supplied by more comprehensive and systematic treatises. The author, however, should have revised in this edition the sections treating of the third stage of labor, the use of ergot, *post-partum* hemorrhage, diseases of the breast, and puerperal fever. While these sections contain much that is true and valuable, a careful revision would have eliminated some errors of principle and practice, and have introduced more modern views. With these exceptions we have only commendation for the subject matter of the book, and doubt not that this edition will meet with the same approval accorded its predecessors.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

240. Experimental Researches Respecting the Relation of Dress to Pelvic Diseases of Women. By J. H. Kellogg, M.D., Battle Creek, Michigan. From the *Transactions of the Michigan Med. Society*, 1888. 22 pages.

241. La Trepanación en la Epilepsia. (Trephining for Epilepsy.) By Dr. D. Enrique de Areilza. Triano, Vizcaya, Spain. 16 pages.

242. Progressive Muscular Dystrophies. By B. Sachs, M.D., New York. From the *New York Medical Journal*, December 15, 1888. 44 pages.

240. This pamphlet contains an account of the result of a series of experiments to demonstrate the effects of tight lacing on the pelvic and thoracic organs, and it leads the author to believe that many ailments peculiar to women are directly traceable to her present style of dress. He, therefore, advises her to resort more to the physical activities characteristic of savage life, and to adopt clothing which secures freedom of motion to the whole body. Dr. Kellogg's experiments are extremely interesting and valuable, especially as they confirm the views in regard to the influence of clothing in producing the costal type of respiration in women which were published by Dr. Mays, of Philadelphia, nearly two years ago.

241. As indicated in our notice of a former pamphlet by Dr. Areilza, in the Reporter, January 28, 1888, he is an enterprising practicer of cranial and cerebral surgery. In the pamphlet now before us he discusses the value of trephining in epilepsy, and gives the histories of two cases, in one of which he operated for the relief of true epilepsy, extirpating the cortical area presiding over the muscles affected in the convulsions, while in the second he trephined, opened the dura and removed a small fungous growth. The result of these operations was at least a temporary relief. He does not venture to say it will be permanent, although he hopes it may be.

Like his former essay, this paper bears the marks of courage in action and of careful study of the subject. It is very interesting, and deserving of the attention of all students of cerebral surgery.

242. Dr. Sachs defines progressive muscular atrophy as a form of disease in which a primary progressive wasting of some or all of the muscles of the body is the most characteristic feature, and in which this wasting (atrophy) may or may not be associated with true or pseudo hypertrophy of some muscles. In this classification he excludes muscular atrophy following cerebral, myelitic, or peripheral nerve-disease. His pamphlet discusses with great fulness and completeness the forms of disease covered by his definition, and leads up to a classification which he proposes as founded upon a correct understanding of them. His paper also contains a useful bibliography of the literature of this interesting and somewhat obscure subject.

—The *Memphis Journal of the Medical Sciences* is the name of a new monthly magazine published in Memphis, Tennessee. It has a corps of six editors, who have charge of separate departments. The first (March) number contains 32 octavo pages of reading matter, and makes a good showing. Price, $2 a year.

CORRESPONDENCE.

Death of a Fœtus from Knotting of the Umbilical Cord.

To the Editor.

Sir: I was called March 23, 1889, to see Mrs. T., white, 42 years old. I found her in labor at full term, the os well dilated, and the pains severe. There was an abundance of amniotic fluid, so much so, indeed, that I could not feel the child until my finger was introduced well up into the uterus. The child's head was found directly over the os. I then ruptured the membranes, and I believe a half-gallon of liquor amnii came away.

The child was born within fifteen minutes, with the umbilical cord around its neck; and the cord near its centre was tied in a firm knot. The child was dead and evidently had been for three or four weeks.

It was quite dark in color, and so was the cord up to the knot; but above the knot the cord was healthy looking.

The patient stated that she had not felt the child move for four weeks. It weighed eight pounds when born. The death of the child was due, no doubt, to the fact that the cord was tied in a knot.

I report this case as I never heard of a similar one.

Yours truly,
G. G. Morris, M.D.

Washington, D.C.,
March 26, 1889.

Infectiousness of Tuberculosis.

To the Editor.

Sir: The Editorial in the Reporter, March 16, on the infectiousness of phthisis, reminds me of the photograph of a tuberculous finger on the hand of L. Barton, M.D., living some seven miles north of Essex, New York, which I saw in 1876, published in the Transactions of the Medical Society of the State of New York for 1871. The finger as represented was double its natural thickness, with tubercles all over it. The account says: "In June 30, 1840, in making an examination of the lungs thirty hours after death, of a subject that died of tubercular phthisis, I accidentally cut the middle finger of my left hand, over the first joint; the wound was slight, not penetrating through the true skin. The wound healed kindly, but remained somewhat red around the cut. In about two weeks inflammation set in, and a row of hard tubercles appeared in the line of the cut, about the size of millet-seeds. In two weeks a second and more numerous crop appeared; in this way the disease progressed for two years in spite of all means suggested, till it had extended from the nail half way to the second joint, and half way around the finger, producing a fungoid thickening of the skin, which was removed with caustics. It was finally cured by the continued use of powdered nitrate of silver."

This is an abbreviated account as there published. After seeing the photograph from this case of inoculation, I concluded that the exhalations and expectoration from a patient with phthisis must be infectious; and soon afterward I was confirmed in this opinion by the death of a mother and daughter, who had been well and hearty when they began attending upon the husband and father, who was suffering with phthisis. The patient's free, thick expectoration covered a large surface of newspaper lying on the floor when I visited him. A few months after his burial, I was told that his wife had consumption; she soon died; and then it was announced that the daughter had it, and she too soon died. It was during our warmest weather when I witnessed this unpleasant spectacle; and that sad ending of mother and daughter seemed plainly to show that the bacillus was active in that fatal deed. Many other similar scenes recur to my memory.

Yours truly,
E. Vanderpoel, M.D.

New York,
March 22, 1889.

Alopecia Areata.

To the Editor.

Sir: The patient, A. S., 36 years old, was a man of seeming perfect health, and of a nervous temperament. He states that one morning in September last, as he was preparing to shave, he ran his fingers over his scalp for a loose hair and was surprised to find he had a handful. Having prided himself on his head of dark hair, his astonishment was profound when after about ten days he presented himself without a *hair on his body*. The scalp was as smooth as though it had been for years as bald as now. After about a month his head showed an occasional white hair, but even at this time, with the hair evidently coming in anew, there would be but little difficulty in numbering those upon the head and face. The patient has never had any constitutional

disease nor any long sickness, and if he had not happened to have at the time a slight erythema of the chest he would have felt even better at the time of the accident than at any time for years.

Yours truly,

MILES D. GOODYEAR, M.D.

Groton, N. Y.
March 21, 1889.

NOTES AND COMMENTS.

Professor Agnew's Farewell.

Professor D. Hayes Agnew delivered, on April 5, his last lecture as John Rhea Barton Professor of Surgery in the University of Pennsylvania, although he will continue to lecture in the Hospital. In honor of the occasion the students had filled the amphitheatre with tropical plants and cut flowers which encircled the space in which the lecturer was to stand. On a bank of roses was a small sheet of paper with this inscription:

"Professor D. Hayes Agnew, as a token of the love and respect of the members of the Class of '89, and with their wishes that he may 'live long and prosper.'"

Dr. Agnew, when he entered the lecture-room, was somewhat astonished at the flowers, and looked around for a few moments bewildered. The applause which signalled his entrance was loud and long continued. After a simple bow of acknowledgment the distinguished surgeon proceeded, without any flourishes, to deliver a brief lecture on tracheotomy. When he had finished, Dr. Agnew paused briefly, and then said:

"And now, gentlemen, I have delivered the last of the lectures that it has been my privilege and my pleasure to deliver to you. In taking my leave from the associations of nearly my whole lifetime, I cannot do so without dwelling for a moment on the reflections that this occasion gives rise to. I have been connected with this institution from its early days, through its rapid growth, to where it stands to-day in the front rank of the medical institutions of the country. With a feeling of satisfaction that I can thus behold this institution which we love so dearly, I turn to contemplate the retirement which I have sought. I feel like a galley-slave with the manacles thrown off and breathing the air of freedom.

"There comes a time in the life of every man when he wants to be free. For over forty years I have been—as they say in the-atrical parlance—on the boards, before the public, and as I glance back over that long period of almost a lifetime, three most delightful thoughts occur to me. The first of these is that, at no time have I ever been received by any act of discourtesy or unkindness by any of the gentlemen whom I have had the honor to address here. The second is that the post of responsibility which it has been my cherished privilege to hold here was one that I had never sought nor asked for. It came to me unbidden. And the third thought is that God has given me the sense, the good sense, to resign it while I feel that I am yet in the full enjoyment and possession of all my faculties. These I have endeavored to strengthen, to broaden, and to render useful in the sphere of my professional life, for I feel that I have lived to very little account if I have not lived to learn.

"In a few days we part, some of us, perhaps, to meet no more. You have chosen a profession which is one of the highest and noblest that a man can make his calling. See that by your faithful zeal and application you endeavor to maintain it in all the dignity that belongs to it. As we take this leave I wish that all of you may prosper; that it may be your aim to elevate your lives, and to round them off in the fulness of an undeviating regard for duty and a high purpose; that, in short, you may be good men and true, good physicians and pure, and good citizens and honorable. I trust, in the effort to attain these high marks in the life that stretches out before you that you may continue in a reverent regard for the faith that has sustained you, guarded you from the paths of evil."

At the conclusion of Dr. Agnew's farewell, the large lecture-room resounded with applause and cheers.

During the lecture and the farewell address, Professors H. C. Wood, Joseph Leidy, James Tyson, T. G. Wormley, J. William White, E. T. Reichert, William Goodell, and other members of the faculty, occupied seats in the enclosure.

Antiseptic Saccharin Dentifrice.

Dr. Constantin Paul proposes the following formula for an agreeable dentifrice:

Saccharin	gr. cl
Bicarbonate of soda	gr. lx
Proof spirit	f℥iii
Oil of peppermint	gtt. xx
Tincture of cochineal	q.s.

—*Chemist and Druggist*, Jan. 5, 1889.

Treatment of Tapeworm.

The following from the *Boston Med. and Surg. Journal*, March 7, 1889, will be interesting in connection with the communication from Dr. Traill Green, published in the REPORTER, April 6, 1889:

Bérenger-Férand, who has written an authoritative book "On the Tæniæ of Man," has communicated to the *Bulletin Général de Thérapeutique*, February 15, 1889, an article in which he sums up the cases of tapeworm,—in all one hundred and ninety-one patients—at the Maritime Hospital of Toulon during the year 1888, and the results of treatment.

Of these 191 patients treated for tapeworm 112 were discharged cured, the worm being expelled head and all; in every instance the tænia was of the variety known as *Tænia inermis*. In 87 instances but one parasite was found; in 11 there were two; in four there were three; in one there were five; in two there were six; and in one unparalleled case seventeen heads were counted as the result of an anthelmintic.

As for the time during which these patients had been afflicted with the parasite, four had carried their tæniæ for three years; two for eight years; and one for eleven years.

As regards the treatment, Bérenger-Férand still gives the preference to pelletierine. This tænicide, which is the active principle of pomegranate bark, is by far the most successful of all remedies used. During the year 1888 pelletierine was employed one hundred and fifty-two times as a tænifuge at the Toulon Hospital. Of these cases one hundred and ten were successful, forty-two were unsuccessful, giving 72 per cent. of recoveries.

As for the manner of administration of the remedy, the patient takes nothing but bread and milk for supper the evening before; the next morning thirty centigrammes (five grains) of the sulphates of pelletierine and isopelletierine are administered in solution with fifty centigrammes (8 grains) of tannin (or half a bottle of Tanret's solution of the mixed pelletierines, the other half to be given in an hour); from 7.30 A. M. to 8 A. M. a full dose of a tablespoonful of the German tincture of jalap is given, or from an ounce to an ounce and a half of castor oil. A few hours after the ingestion of the medicine the patient experiences a slight vertigo, and the tapeworm is voided, as a rule, four hours after the dose is taken. In order to avoid breaking of the worm during its passage, and before the head is voided, it is advised that the patient shall sit at stool in a vessel nearly full of warm water. Bérenger-Férand has lately resorted to injections of a decoction of pomegranate bark to assist the expulsion of the worm, and claims that this is an improvement in the treatment.

It is needless to say that the above is now the favorite treatment of tænia in France, and Dujardin-Beaumetz affirms that "since we have established these rules of treatment, and wherever patients have scrupulously complied with them, we have had numerous successes, and in nine cases out of ten we obtain the worm with the head."

Bérenger-Férand finds in his last year's experience in the treatment of this painful malady gratifying confirmation of the results obtained in past years.

Sharpening the Section Knife.

The *St. Louis Med. and Surg. Journal*, March, 1889, says that judging from the number of queries which are made from time to time, and from the interest displayed by students and others on this point, sharpening the section knife, while simplicity itself to one who has learned the "knack," is one full of difficulties to the uninitiated. Giving in succession three or four students who complained that they could not succeed in getting the right kind of an edge on their blades, an old knife and a hone, and closely watching their manœuvres, what appears to be the prime cause of the trouble is seen to be an involuntary turn of the wrist upward at the end of each forward and backward motion of the knife on the hone, whereby the edge placed on the blade at the centre of the stroke is rounded off and worn away. There is another habit, also quite common, which has a similar effect on the edge, viz., the reversing of the blade at the end of a stroke on its edge, instead of on its back, as a fulcrum. The blade should be laid on the surface of the hone in such a manner that every part of the flat side is in contact at one and the same time, and this contact should be maintained throughout the stroke. On the hollowed side the cutting edge and the edge of the back should be kept constantly on the surface of the hone. The knife should be drawn over the stone *edge foremost* with a smooth, even stroke, from heel to point. Where the knife is very dull or hacked, most of the honing should be done on the hollowed side, for obvious reasons. As to hones: some difference of opinion exists as to the relative merits of the Turkish, the "barber" or "German razor," and the

Ouachita or Hot-Springs stones. Each has its merits. The Turkish hone cuts more rapidly than either of the others, but leaves a wiry edge that must be strapped off. The "barber," if a good specimen, leaves little to be desired on the score of either rapidity of cut or smoothness of edge; but for a perfect edge, requiring no strapping, the finer qualities of Hot-Springs hones are unexcelled. Other things being equal, the hone with the broadest bearing surface is the best. As a lubricator olive oil should be used with the Turkish stone, soap-suds with the "German razor," and pure glycerine with the Arkansas hones. As to "strops," unless they handled in a gentle and scientific manner they always do more harm than good, by rounding off the edge.

General Paralysis Associated with Locomotor Ataxia.

Dr. A. Strümpell communicates to the *Neurologishes Centralblatt*, No. 5, 1888, an account of a case in which he thinks that under the influence of syphilis general paralysis and locomotor ataxia developed together in the same person. The patient was a girl 13 years old, whose father had contracted syphilis two years before the birth of the child. The child had always been delicate and subject to skin eruptions. When thirteen years old it was attacked with transient paralysis of the whole of the right side. This paralysis disappeared in half an hour, but reappeared fifteen days later complicated with aphasia. Similar attacks recurred subsequently every three or four weeks for a year. After the first attack a decline in the intelligence of the child was noted. Subsequently, embarrassment of speech persisted; the gait became unsteady; and pain was complained of in the belly and in the side.

The chief symptoms noted by Strümpell at his first examination about twenty months after the first attack, were: Very pronounced enfeeblement of the intellect, entirely characteristic embarrassment of speech, shaking and trembling of the muscles of the face, when the patient spoke, difficulty in writing such as is manifested in patients with general paralysis—forgetting letters, syllables, or entire words—abolition of reflex movements of the pupil, trembling of the tongue, unsteady movements of the arms, very pronounced ataxia of the lower limbs, abolition of the knee jerk, blunting of the sensibility to pain.

Iodide of potassium seemed to improve the condition of the lower limbs and of the speech. Then the disease resumed its progress. Six months later the patient had a fresh and violent attack of paralysis which lasted half a day.—*Gazette médicale de Paris*, Jan. 12, 1889.

Scarlet Fever, Diphtheria and Measles in New York City.

The prevalence in New York City of scarlet fever, diphtheria and measles is shown by the statistics of the Board of Health for the month of March. The cases of scarlet fever numbered 1709, while for the corresponding month of last year they numbered only 613. Cases of measles have increased from 236 in March, 1888, to 800 in March, 1889. Diphtheria shows a much smaller percentage of increase, the number of cases for March, 1889, being 811, while in the corresponding month last year the number was 534.

The spread of these diseases is attributed in part to the neglect of disinfection by the attending physicians, and in part to carelessness in the matter of isolating patients.

Commencement of Jefferson Medical College.

The sixty-fourth annual commencement of Jefferson Medical College of Philadelphia was held April 3, 1889, and the degree of Doctor of Medicine conferred upon two hundred and twelve graduates. The following prizes were awarded:

A prize of $100, offered by *The Medical News* for the best thesis embodying original research, to Michael Valentine Ball, of Pennsylvania; a gold medal, for the best essay on a subject pertaining to the practice of medicine, to Joseph John Burke, of Pennsylvania, with honorable mention of the essay of Thomas Clinton Seright, of Ohio; a gold medal, for the best anatomical preparation, to Howard Roeder Swayne, of Pennsylvania; a case of instruments, for the best examination in materia medica, to Ellis Freedom Frost, of Rhode Island; a case of instruments, for the best examination in surgery, to Malcomb Wayland Everson, of Pennsylvania; a gold medal, for the best report of Dr. Thomas G. Morton's surgical clinic at the Pennsylvania Hospital, to Ross Parker Cox, of Georgia, with honorable mention to George D. Thomas, of the undergraduate class.

The valedictory address was delivered by W. S. Forbes, M.D., Professor of General, Descriptive and Surgical Anatomy.

NEWS.

—Dr. Wilbur P. Klapp and Dr. Lewis H. Adler, Jr., have been elected Resident Physicians at the Episcopal Hospital.

—The Training School for Nurses of the New York Hospital conferred diplomas on fourteen graduates on April 4.

—The thirty-second annual meeting of the Missouri State Medical Association will be held at Springfield, May 21, 22 and 23.

—At the eighth annual commencement of the Medico-Chirurgical College April 4, the degree of Doctor of Medicine was conferred upon 30 graduates.

—The mortality reports of the city of Philadelphia continue to be favorable, and the returns for the week ending April 8 show a smaller proportion than usual of deaths from such diseases as scarlet and typhoid fevers and diphtheria.

—The Dean of the Faculty of the Woman's Medical College of Pennsylvania has announced that the Faculty are prepared to advocate the proposed amendment to the Medical Examiners' bill, which makes the course of medical study four years.

—Passed Assistant Surgeon Hervey W. Whitaker, of the Navy, who is at present attached to the nautical school-ship St. Mary's, has been appointed clinical assistant to the chair of hygiene at the Post-graduate School of the College of Physicians and Surgeons, New York.

—The second annual address before the Society of the Alumni of Bellevue Hospital was delivered April 3, at the Academy of Medicine, by Dr. William Osler, Professor of Medicine in Johns Hopkins University. Dr. Osler's subject was "*Phagocytes.*" After his lecture he was given a reception.

—Dr. George B. Loring, who has just been nominated as Minister Resident and Consul General to Portugal, was graduated in medicine at Harvard, in 1842. He was surgeon to the Marine Hospital, Chelsea, Mass., from 1843 to 1850, and a Commissioner to revise the United States Marine Hospital system in 1849.

—Dr. Benjamin Lee, Secretary of the State Board of Health of Pennsylvania, who represents the interests of the Middle Atlantic District, has gone to Florida to confer with a commission of sanitary officials, recently appointed by the Legislature of Florida, with reference to the proper means to adopt to prevent a recurrence of yellow fever in that State.

OBITUARY.

PROF. FRANCIS CORNELIUS DONDERS.

Prof. Francis Cornelius Donders, the well-known Dutch doctor and eye specialist died very recently at the Hague. Dr. Donders was born at Tilburg, in Brabant, May 27, 1818. He studied medicine at the Military Medical School at Utrecht, became military surgeon at the Hospital of The Hague and afterward professor at the Utrecht school. He was subsequently called to the university of the same city, and became successively professor of histology and physiology, and then of ophthalmology, to which was added the clinic of diseases of the eye. In 1863 he obtained from the Government the title of professor, and was voted a sum of money to construct a physiological laboratory corresponding to the needs of modern science, where many delicate and valuable researches have since been carried out.

Dr. Donders is best known for his researches on the physiology and pathology of the eye, and for his works on Astigmatism and on Anomalies of Refraction. In them he treated the eye as an optical instrument, showed that it was liable to cause distorted images on the retina with corresponding defective vision, and concluded with profound researches on lenses, prisms and cylinders of glass as means for correcting these errors of refraction.

RESOLUTIONS ON THE DEATH OF DR. BRUEN.

At a meeting of the Medical Staff of the Philadelphia Hospital, held April 1, 1889, the following resolutions were adopted:

"Whereas another vacancy on our Staff has been created by death,

"Resolved: that by the death of Dr. Edward T. Bruen, who was an indefatigable worker, a clear thinker, and an able writer, the interests of scientific medicine have suffered severe loss.

"Resolved: that while this loss will be felt by every medical practitioner, it is but slight compared with that experienced by numerous personal friends to whom he had endeared himself by many amiable qualities.

"Resolved: that the sincerest sympathy of the Staff of this hospital be tendered to the family of their late colleague.

JAMES TYSON,
President.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

EFFERVESCENT SPECIALTIES

WM. R. WARNER & CO.'S

TRIPLE

(Effervescent)

BROMIDES

Advantages:—Useful in Headache, Nervousness, Sleeplessness, Migraine, Diurnal Epilepsy, Etc.

℞ Sodium Brom. grs. 15.
Potassium Brom. grs. 10.
Ammonium Brom. grs. 5.

Administer one teaspoonful in half a glass of water. Drink while effervescing. In Diurnal Epilepsy take a dessertspoonful three times daily until sense of taste is partly destroyed; after this reduce the frequency of dose, but keep the fauces in a benumbed condition.

WM. R. WARNER & CO.'S

CHALYBEATE

(Effervescent)

SALINE

(Ferric Saline Effervescens, Dr. Means)

℞ 1 gr. Citro-tartrate of Iron and 20 grs. of Soda.

DOSE.—A heaping teaspoonful of the salt, containing 1 gr. Citro-tartrate of Iron and 20 grs. of Soda, to be taken in a glass two-thirds full of water and drunk while effervescing. If a more decided effect is desired, warm instead of cold water may be used. In all cases this draught should be taken but once or twice a day, and then on an empty stomach, preferably before breakfast. No restrictions as to diet. One or two Pil. Digestiva (W. & Co.) may be taken at noon, before eating, as a dinner pill.

WM. R. WARNER & CO.'S

(ANTIPYRINE ET SODIUM SALICYLATE)

ANTALGIC

(Effervescent)

SALINE

℞ Antipyrine, 4 grs. Salicylate of Soda, 4 grs.
In each dessertspoonful.

DOSE.—One dessertspoonful, to be repeated as often as the case may require Almost a specific in Neuralgic Headache. Prescribed in all cases where Antipyrine is used, with more better and more certain results.

WM. R. WARNER & CO.'S

APERIENT

(Effervescent)

SALINE

A pleasant and excellent aperient and refrigerant, very acceptable to the stomach. Given in all cases indicating the need of an active aperient, and to be given daily to all patients under treatment with Dosimetric therapeutics. (See Wm. R. Warner & Co.'s Dosimetric Granules.)

DOSE.—One tablespoonful in half a glass of water.

PREPARATIONS SUPPLIED BY ALL LEADING DRUGGISTS.

☞Samples of the above Salts furnished upon request.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

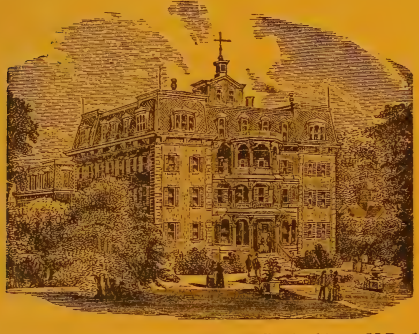
4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO.,

PHILADELPHIA.

BURN-BRAE.



This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

DUODENAL ULCER; SUDDEN ENORMOUS HEMORRHAGE; DEATH.[1]

BY WILLIAM PEPPER, M.D.,

PHILADELPHIA.

PROFESSOR OF THEORY AND PRACTICE OF MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA.

The man from whom these specimens were obtained was about thirty-five years of age. He was a prominent athlete, had taken part in many contests requiring strength and endurance, and had distinguished himself on many occasions as a runner and an oarsman. He had been suffering more or less constantly for eight years. He was a man of generally careless habits, and this was especially noticeable in the irregularity of his meals and in the want of care he displayed in selecting his food and drink. His first complaint was of epigastric pain. He had irregular attacks of this at first, and these gradually became more frequent, prolonged, and violent. They were partly relieved by firm pressure over the immediate seat of pain. His suffering was attributed to gastralgia, and his only remedy was this forcible pressure, to which he always resorted.

It was not long, however, before it became clear that something more was the matter than simple gastralgia. The existence of gastric catarrh was noted, and, in time, another symptom was developed: he began to vomit. At first this was occasional, then it occurred several times a week, and, finally, it became of daily occurrence and so continued for several years. For this trouble he sought medical advice, but with only temporary benefit. Among other things, a milk diet was directed for him. This, he thought, seemed beneficial. It afforded him some relief from his constant pain and he kept it up largely for this reason. He had a craving sense of discomfort and irritation, and, to allay this, he

[1] Delivered at the Hospital of the University of Pennsylvania.

drank prodigious quantities of milk. When the pain happened to be especially annoying he would drink a pitcher-full of cold milk at a draught. This did, indeed, give him some ease, but it was merely transitory and he was soon again in distress. Previous to his illness he had been addicted to the use of wine and tobacco, both in excess; but soon after the commencement of his gastric trouble he entirely abandoned them. We cannot know, therefore, in what manner the administration of stimulants would have influenced his symptoms. He preferred bland, cooling drinks, and these, as you see, he used in large quantity. He lived in this way for a long period, working hard, keeping up his exercise, and maintaining an appearance of good health. There was no emaciation.

Two weeks ago to-day, that is on Saturday, he went to his office in the morning and, on approaching his desk, suddenly fainted and fell to the floor, vomiting an enormous quantity of blood. Everything near him was deluged with the fluid, and he must have lost a quart at least. Immediate assistance was rendered him; he was removed to the house of a relative, and powerful restoratives administered. I saw him about noon and found him in a state of partial collapse, with cold extremities, a thready running pulse, and all his tissues blanched from the great loss of blood.

With the foregoing history that I then obtained and the sudden and violent hemorrhage, I confidently diagnosticated the existence of a gastric ulcer, and felt some surprise that it had not been recognized much sooner. There was no difficulty in excluding cancer, for the pain had been of much too long standing for that disease; there had also been no obstruction of the bowels, and there was no emaciation. It could not be an instance of rupture of an aneurism, for there had been nothing which would indicate the presence and growth of an aneurism. The man had been uninterruptedly pursuing his business and exercise, there was no arterial rigidity, and there had been no shortness of breath. The only other question was as to cirrhosis of the liver. I have before dwelt upon the fact that cirrhosis of the liver will not only frequently occasion a violent gastric hemorrhage, but that this sudden hematemesis is often the first *severe* symptom of that disease. This startling event may, indeed, be quickly followed by a long train of the commoner symptoms of the disease—disordered digestion, hemorrhoids, distension of the abdominal veins, ascites, etc.—but until the occurrence of that hemorrhage, they may all have remained entirely latent. In this case we had a prolonged history of generous living and of a gastric catarrh extending over several years; but I found that the patient had not been in the habit of consuming strong spirits and it is only these, as a very general rule, that produce cirrhosis. Again, this man had for a long time experienced severe pain which was relieved by pressure and by the imbibition of cool drinks; whereas in cirrhosis the pain is not violent and is not mitigated by either of these measures. I did not attempt to make any careful examination at the time, but I satisfied myself that the liver was not materially diminished in size. Taking all the more striking features of the case into consideration, therefore, I determined that it was one of gastric ulcer.

The treatment adopted consisted of very simple remedies. The patient was kept completely at rest, ice bags were placed over the stomach, and, at intervals, small pieces of ice were swallowed. A pill of nitrate of silver and opium was given, and the nourishment consisted of small quantities of milk and lime water. Evening found the patient in better condition and quite cheerful. His only complaint was of constant thirst. During the night, however, he became restless, there was a return of epigastric pain and discomfort, and with the coming of dawn another hemorrhage occurred. Again the quantity lost was fully a quart. I neglected to mention that on the preceding day the patient had taken a few doses of Monsell's solution. In spite of this, however, the ulcer had either been bleeding continuously during the night, or else a vessel had suddenly given way in the morning and occasioned this abrupt gush of blood. I think the latter of these views is the more probable. The patient again sank into a state of profound collapse, and in the evening was barely living.

At this time I called Dr. White to see the case with me, with a view of employing transfusion to revive the rapidly ebbing life. From this time until the following Saturday evening, when death occurred, the patient was under continuous observation, Dr. Daland remaining with him day and night. During the seven days over which this acute illness extended, the thirst was incessant and insatiable. This is without doubt the most pitiable symptom in these cases. The sufferer cries in agony for drink and yet, in dread of provoking another

hemorrhage, we can permit only the smallest quantities of liquid to be given. The supplies of milk and lime water were now alternated with small doses of champagne and Apollinaris water, mixed in the proportion of one part to three, and then partly frozen at a neighboring confectioner's. This proved very grateful to the parched throat of the patient. To support his strength the measures chiefly depended upon were nutritive enemas and the hypodermic administration of powerful diffusible stimulants.

Ether, digitalis, atropia, and morphia were given in sufficient amount to control the restlessness and distressing thirst and to stimulate the heart. It was only by the frequently repeated use of these potent remedies, that life was prolonged during the several days that followed the occurrence of the primary hemorrhage. I have no doubt whatever that had they been withheld for a few hours only, death would have promptly taken place. During the day following the second hemorrhage, on Monday, it became evident that something else would have to be done to rouse the patient from the state of fatal collapse into which he was sinking. It was decided to resort to transfusion. At one o'clock Tuesday morning a hot saline solution, an artificial serum, was injected into the left median basilic vein. This was accomplished without accident and its immediate effects were very gratifying. Unfortunately, however, they were maintained for only a few hours, the patient relapsed into his former condition, and the operation was not repeated. Nothing was now left us to depend upon but frequent supplies of concentrated liquid nourishment, and stimulants. The stomach had become quiet and a slightly increased quantity of fluid was permitted.

Now, however, an unfortunate complication arose. Fever made its appearance, and the temperature steadily rose to 102°, 102.5°, and 103°, Fahr., where it remained until the end. The proper explanation of this fever was difficult at the time, and it still remains somewhat clouded. It was probably due to a combination of several causes, and some of these I will detail. We found that if we wished to continue using the rectum as a medium for nourishing the patient, it would have to be emptied and cleansed. An injection given for this purpose procured the discharge of a great quantity of black, tarry, fetid blood, the stench of which was indescribable. It was diffused throughout the whole room in a moment. This evacuation was evidence that at the time of the discharge of blood from the stomach, a large quantity had made its way into the intestine, and, remaining there, had undergone decomposition. It was clearly necessary to rid the intestinal canal of this rotting mass, for it was acting not only as a powerful excitor of gastro-intestinal irritation, but also as a source of septic poisoning. These two factors were quite sufficient partly to explain the rise of temperature. As an additional explanation of this symptom, I thought it probable that some inflammatory action had been excited around the seat of the ulcer. The results obtained from the autopsy showed that all of these causes had been active in producing the febrile condition. Large enemas, to which Listerine was added, brought away large quantities of blood of a gangrenous odor, and subsequently, hot concentrated saline solutions were given in the same manner with the effect of causing still further evacuations of a similar character. But, notwithstanding the fact that at least four pints of this offending material were removed in this way, the *post-mortem* examination revealed the presence of certainly as much more.

It is clear, therefore, that coincidently with the profuse gastric hemorrhages, an enormous amount of blood passed downward into the intestines. We need but little besides these three conditions—the frightful loss of blood, the subsequent severe irritation of the gastro-intestinal tract, and the septic infection produced by the local changes in the effused blood—to account satisfactorily for the rise of temperature. In instances of gastric hemorrhage a certain amount of overflow into the intestinal canal is quite common — sufficient, usually, to produce one or two dark stools; but I do not think I have ever met with a case in which the quantity of blood entering the intestine was so excessive as it was here.

The patient's prostration gradually became more profound, and death finally occurred from heart failure and cerebral exhaustion, accompanied with persistent high temperature, but with no recurrence of hemorrhage. We could not tell positively whether or not some oozing into the intestinal canal had been continuing during the final days of the illness, but I did not think this probable. Two other points in connection with the case remain for consideration. First, there was a heart murmur. This was heard most distinctly over the left edge of the sternum and was systolic in time. It seemed plausible, in view of the great loss of blood, that

this was anemic in character; but its position did not conform to that usually occupied by murmurs dependent upon that cause. The problem was as to whether or not it was the result of valvular change. The second and last point to be mentioned is, that the urine was albuminous. It contained no casts, however. It is not improbable that this abnormality was occasioned by altered conditions of blood-pressure, and possibly also, the operation of transfusion may have had some bearing upon it. The body was embalmed shortly after death and the examination then made.

Let us look at these specimens together, taking the heart first. We see at a glance that the murmur was organic—an aortic systolic murmur. The condition found here is remarkable for such a comparatively young man, and is suggestive of protracted and violent overstrain. The valvular flaps are fenestrated and there are several nodular elevations upon and around them. It is evident that they permitted some regurgitation. The walls of the aorta are slightly atheromatous. As to the kidneys, the considerable blanching of these organs by the fluid used in the embalming process, interferes to a great extent with an accurate recognition of their condition, but I venture the assertion that they are somewhat fatty. We now take up the viscera that will determine for us the cause of the hemorrhage. We have here a stomach that displays unmistakable evidences of frequent overdistension. It is enormously dilated, its walls are thickened, the rugæ of the mucous membrane are prominent, and it bears all over its mucous surface the lesions of a chronic catarrh. In some few places the mucous membrane has been thinned; *but upon no part of it is there a sign of an ulcer!* Let us pass to the duodenum. We find it, proportionately, as much dilated as is the stomach. It averages fully eight inches in circumference. Just here, about an inch beyond the pyloric orifice of the stomach, we find a loss of substance which completely encircles its inner surface. Within the limits of this breach of tissue we discover the ragged extremities of a branch of the pancreatico-duodenal artery, which has been ulcerated completely through.

Here, then, is the solution of the whole case. We were dealing with an extensive duodenal ulcer. This lesion is encountered much more rarely than is gastric ulcer, and it is, almost in the same degree, more grave. This is the most striking case of the kind that I have ever seen. There seems to have been no attempt at closure of the divided ends of the artery, by the formation of firm clots. It seems somewhat probable, therefore, that continuous bleeding may have taken place from the time of the last severe hemorrhage until shortly before death. Being only slowly effused, however, the blood passed quietly down into the lower bowel and there accumulated. It was only when the sudden and violent gushes of blood occurred, that the pyloric opening of the stomach was burst through and the excess of fluid ejected by the mouth.

This rather full recital of this man's illness and death, will doubtless impress upon your minds the difficulties of diagnosis and of treatment in such cases, and the very grave dangers which constantly threaten the patient. In looking back over my conduct of the case, I cannot think of anything omitted which might have added to his chances of recovery, nor do I think that anything was done which might have diminished what few chances he had. It was, of course, too late to have hoped to effect a permanent cure. The patient himself was largely responsible for his death, in that he constantly neglected the commonest rules of health, and postponed, until a hopelessly late day, submitting himself to the care of a physician.

COMMUNICATIONS.

OBSERVATIONS ON PUERPERAL ECLAMPSIA.[1]

BY B. F. RECORDS, M.D.,
SMITHVILLE, MO.

Gentlemen: I am aware of the magnitude of the subject I have undertaken to bring before you; also, that it may appear to you presumptuous for a mere country practitioner to attempt to write anything on a disease, the etiology and treatment of which have puzzled the closest observers, as well as having been the source of controversy amongst the ablest writers and thinkers in our profession. My only excuses for my presumption are: first, the rarity of the disorder: it being so rare indeed that the general practitioner sees but a few cases in a life-time, and hence the necessity of occasionally reviewing it, in order to be prepared to meet it when called upon as we generally are when least expecting it. Another reason

[1] Read before the Kansas City District Medical Society, March 14, 1889.

is, that as an old practitioner I have seen a good many cases, and formed my own conclusions; not, however, independently of the observations of others more able than myself; yet, they may be somewhat at variance with the opinions of the Fellows of this society—how much remains to be seen.

Etiology.—I see no reason to doubt that albuminuria is the prime cause of puerperal eclampsia. I believe from my own observation, and careful investigation of our best authors, that the mechanical interference with the circulation, occasioned by the enlarged uterus, together with the larger quantity of blood required for the nutrition and development of the fœtus, imposes a greater amount of work upon the heart, the left ventricle of which becomes hypertrophied to compenaste for the extra work thrown upon it; thus placing the kidneys on a strain correspondingly, and by these combined forces, brought into and kept in continued action, the latter organs become irritated by overwork and the pressure of the gravid uterus upon the renal vessels, and so allow the superabundant albumin to escape. Dr. W. H. Parish, Obstetrician to the Philadelphia Hospital, in a communication published in the MED. AND SURG. REPORTER, vol. xxxv, said: "Physiologists tell us that the modifications in this (the puerperal state) consist in a lowered specific gravity, an increased amount of water, an increase in the entire bulk of blood, an increase in white blood corpuscles, an increase in urea and in fibrin, a deficiency in the number of red blood-corpuscles, and a deficiency in albumin; also, the disturbance in respiration permits the retention in the blood of more than the normal amount of carbonic acid. There is, in other words, a plethora, a fulness of the entire vascular system, but plethora of hydræmic blood, with a deficiency of those elements destined for nutrition, and a superabundance of those elements representative of retrograde tissue metamorphosis, as urea, fibrin, and carbonic acid. Associated with blood alteration there is an increase in the propelling force of the heart; an increased vascular tension incident to an hypertrophied condition of the walls of the left ventricle, this hypertrophy being an accompaniment of probably every case of advanced pregnancy. . . . Again, the nervous system undergoes a modification apart from its disturbed nutrition. . . . The low specific gravity of the blood, its increased amount, and the increased force with which it is driven through the vessels, all coöperate in greatly increasing the process of exosmosis. This is evinced in the tendency to general anasarca. The intra-cranial tissues partake of this general condition, and there is at first an engorged state of their blood-vessels, then, by the increased exosmosis, an œdema of the brain tissue occurs. If this œdema is marked at the central portions, or the base of the brain, then convulsions may be occasioned, especially if to this state of œdema is added an irritable condition of the brain centre incident to perverted nutrition, and if also, this increased intrinsic irritability is aggravated by irritation reflected from the peculiarly sensitive uterine nerves, or even if this reflected irritation originates in some part not included in the generative organs."

Œdema is not always present in women having puerperal convulsions. Two of my cases (Cases III and IX) had no sign of infiltration, yet the urine in both was albuminous, and by examining the urine of all pregnant women it will be discovered that many patients with albuminous urine present not a vestige of œdema. M. Blot found it in 23 out of 41 cases. It is also well known that there are many cases of Bright's disease without dropsy. "Freirich found that, of 220 cases of Bright's disease, 175 were accompanied with œdema, and 45 were free from it." (Cazeaux.)

The kidneys of women dying in puerperal convulsions have been found to present the characteristic anatomical lesions of albuminous nephritis, according to MM. Cazeaux and Rayner: and they found "in them the second, sometimes the third, and only once the fourth degree of alteration." M. Blot "regards puerperal albuminuria as generally unconnected with Bright's disease." So also, "M. Bach, of Strasbourg, thinks that it is only *sometimes* due to albuminous nephritis, and M. Imbert Goubeyre endeavors to prove that it is always a sign of Bright's disease." (Cazeaux.)

As to uræmic toxæmia being the true cause of puerperal eclampsia, as is frequently claimed, I beg leave—with due deference to the great men of the profession who so contend—to differ. That the convulsions and coma which are observed in uræmic intoxication and albuminuria are similar to some extent, I do not deny; but to my mind that is no sufficient reason for believing that it is due to the former instead of to the latter. I think it would be nearer the truth to consider that uræmia and albuminuria are so intimately connected that

their combined influence is required to produce the convulsions and coma of puerperal eclampsia. Dr. Bourneville, in the *Archives de Tocologie*, for April, 1875, says: "1. In the eclamptic state the temperature rises from the beginning to the end of the attack. 2. In the intervals of accession the temperature maintains a high figure, and at the moment the mercurial column registers a slight ascension. 3. Lastly, if the eclamptic state ends in death, the temperature continues to rise, and attains a very high figure; if, on the contrary, the accessions disappear, and the coma diminishes or ceases definitely, the temperature progressively lowers and returns to the normal figure." He adds: "From the first we note a lowering of the temperature in uræmia, and an elevation of temperature in puerperal eclampsia. In the course of uræmia the temperature is progressively lowered, whilst in the course of the eclamptic state it rises more and more from the onset of the accessions, and that with great rapidity. These differences are accentuated at the approach, and even at the moment of death; in uræmia the temperature descends very low, even much below the normal figure; in eclampsia, on the contrary, it attains a very high figure." (*Ranking's Abstract.*) I suppose every one of us can bear testimony to the above evidence of Dr. Bourneville. If so there can be no longer a question as to the cause of convulsions, and the thermometer can decide for us. In the few cases of uræmic intoxication which I have noticed the low temperature and the slow pulse were not to be mistaken.

Whilst puerperal eclampsia is very rare, puerperal albuminuria is very frequent. "Dr. Lantos, of Buda Pesth, has recently made a series of observations on albuminuria of pregnancy in the wards of Professor von Kezmarsky. His paper was published in the *Archiv für Gynäkologie*, vol. xxxii, part 3," an extract of which I quote from THE MEDICAL AND SURGICAL REPORTER, Feb. 16, 1889: "In over 18 per cent. of 70 pregnant women he found albumin in the urine, whilst in nearly 60 per cent. of 600 newly delivered women the urine was albuminous. Albuminuria was detected in over 70 per cent. of 268 primiparæ, and over 50 per cent. of 332 multiparæ. The per centage was distinctly lower in premature labor, and 50 per cent. lower in abortion cases. . . . Out of 14,815 labor cases observed in the course of fifteen years, he noted 53 cases of puerperal eclampsia, a ratio of 278 to 1. Over 78 per cent. out of 42 cases of eclampsia occurred in primiparæ; 15 out of the entire 53 died."

"Pajot found puerperal eclampsia once in 350 cases; Hyernaux, 20 times in 6,370 cases. Its frequency varies with the period of pregnancy; in 200 cases of eclampsia, 60 during pregnancy, 100 during labor and delivery, and 40 during the puerperal state." (Verier.)

Prognosis.—There is no question but that puerperal eclampsia is a serious and dangerous malady. Mauriceau lost 21 out of 42 cases; Velpeau 8 out of 21; Pajot 12 out of 26; Hyernaux 8 out of 20. Madame La Chapelle states that one half of the cases of eclampsia die. In my own cases I lost 1 out of 6, whilst of the patients that I saw in consultation, three in number, *all* died. They were all in a comatose condition from the start, and apoplectic.

The fatality is determined I think by the greater or less quantity of albumin in the urine. Braun has a table of 36 cases which I take from Cazeaux's Midwifery, which is at least evidence of some value.

Albumin was very severe in	3	cases,	2	died.	
"	" " consid'ble	7	"	4	"
"	" only "	14	"	5	"
"	" " moderate	8	"	1	"
"	" " slight	4	"	0	"

There is another condition which may or may not be attended with severe albuminuria, and in my opinion is nearly always fatal; I allude to such cases as go almost immediately into what might be termed *apoplectic coma*. Cases IV, VII, and VIII, were such cases. All three were completely comatose, with stertorous breathing when I first saw them shortly after their first seizure, notwithstanding that they had each had the most approved treatment from the start. The cause of death in Case II, I attribute to the fact that the patient was severely albuminous, and had had eleven convulsions before treatment was begun, and was so completely overwhelmed by carbonic and uric acid as to be beyond medical aid.

There are cases of convulsions during and before labor, in which there is neither albumin nor uric acid. They are hysterical, and are not worth a notice in this place.

A strange feature in the cases that I saw, was that three of them occurred in six months of the year 1879, whilst the remaining six were scattered over a period of *twenty* years, from my first to last cases. Cazeaux met with but 3 cases in 2,000 deliveries at the Hôtel Dieu, and then saw 7 cases from July to October, 1846, at his clinique.

Treatment.—The urine of all pregnant women should be tested (if it can be obtained) frequently during the latter months of gestation; especially if there is œdema, or a falling off in the quantity of urine excreted daily, or if there is headache, or other evidence of failing health. Nine times out of ten, however, the physician in the country is not notified that his services will be required, or that the woman is *enciente* even, until he is wanted in great haste to attend her in labor. Many women are confined and "it is all over," when the doctor arrives. I have when engaged beforehand made it an invariable rule to inquire into the condition of my patient's health, and to prescribe if necessary for any deviation therefrom. I think in this way I have perhaps prevented a few cases of eclampsia; at least no case of eclampsia has occurred in my practice when the patient had submitted to prophylactic treatment. Where albumin is found during pregnancy, milk should be prescribed in large quantities; also such diuretics and tonics as may be indicated. It is a good and safe rule, when called to a case of labor, to inquire about the action of the bowels and kidneys. If necessary, draw the water and boil it; if there is albumin enough to endanger the welfare of the patient this rough test will show it. In such a case institute treatment at once. A large dose of sulphate of magnesia or other active cholagogue should be given, followed by acetate of potash, sweet spirits of nitre, buchu, or digitalis.

Supra-orbital pain is a danger signal not to be slighted, and it often precedes convulsions. Here the purgative dose must be followed by raising the head, applying cold cloths to the forehead, mustard to the nucha, and giving large doses of bromide of potash, with tincture of aconite, repeated every half-hour, or hour or two, as indicated. I believe in one case, at least, I succeeded in warding off a severe attack of eclampsia by following the foregoing plan. If I should meet such a case again, and there was apparent cerebral hyperæmia, with the other prodromata, I should, in addition to the treatment named, take blood until the head was relieved.

There are cases in which there is neither infiltration nor supra-orbital pain, and the first symptom noticed is that the patient becomes restless, tossing about without reason, then the eyes turn to the left, and the head follows the eyes, and instantly a horrid convulsion seizes the patient. In such a case the physician has no time for preventive treatment. What to do just at this time, is an important question. Of course nothing can be done during the convulsion. In most cases a hypodermic of one-quarter to one-half grain of morphine, with a dose of tincture of gelsemium, will give time to bleed if the case demands it, or to use whatever, in the judgment of the physician, is indicated. If the patient is hyperæmic, bleed. If she is hydræmic, administer a purgative, and follow with bromide and aconite, and diuretics between the doses of the latter. Then, if the patient does not become comatose, place her under the influence of an anæsthetic. If labor is fairly on the way, it is to be encouraged. If labor is not begun, the uterus should be let alone. If apoplectic coma sets in early, the case is desperate. A large venesection should precede everything else. It should be carried far beyond the amount usually prescribed, if it is to do any good. From two to four pints of blood, or more, must be taken. A decided impression must be made upon the arterial tension. This is the remedy *par excellence*. No patient with eclampsia who was a proper subject for venesection was ever lost by being too freely bled—or, at least, I think so; but numbers of them, I believe, have come to an untimely grave for the lack of a large bleeding. We have all witnessed the remarkably rapid restoration of women who have had post- or ante-partum hemorrhage until they were left exsanguine. Are we to learn nothing by witnessing the wonderful recuperative power of nature in such cases?

There is another and quite a different condition which we frequently meet. It is a hydræmic condition; just the reverse of the foregoing. Here there may be an appearance of plethora, but it is plethora of watery blood. The patient's skin is white, and infiltrated; the muscles soft; the pulse rapid, tremulous and small. In such cases I believe that the lancet is injurious; though I am aware that venesection has been resorted to without reference to the condition of the blood. I have myself been guilty of just such a lack of discrimination. If the patient survived, it was in spite of my foolish treatment.

The lancet will not cure all cases. Indeed I doubt if alone it will cure any. It is only one of the many means to be resorted to. Now I believe that so far as we are able, we ought to adopt a specific or rational treatment. By that I mean that the particular condition of each case ought to be taken into consideration, and the treatment based on the specific indications.

There should be no routine in the treatment of puerperal eclampsia. Routine treatment is a mark of ignorance, prescribing for a name, instead of for a pathological condition. See what the indications are, and meet them intelligently. If your patient's bowels were loose, and thoroughly emptied in a natural way, you would certainly not give her a quarter pound of salts, or five or six drops of croton oil. If she had lost a half-gallon or so of blood, as may be the case in post-partum convulsions, you certainly would not open a vein. By no means. If nature has already removed the red corpuscles from the blood, and replaced them with white corpuscles, you would certainly not assist nature in destroying the vital principle of the blood further by venesection.

The real remedies in puerperal eclampsia are few. In one case the lancet; in another the hypodermic use of morphia and gelsemium. In another chloral, in twenty to sixty grain doses, by mouth or rectum. In all cases the bromides in forty, sixty or one hundred grain doses, with aconite, and with or without diuretics, purgatives, etc. Then, in some cases, chloroform is the remedy. I do not believe that chloroform or morphia either should be administered where there is deep coma. The reasons for this are self-evident, and need not be discussed. Here the pack should be used, preceded if possible by a bath; but in a country practice the bath is rarely obtainable.

Liebermeister's method is as convenient as any. "The patient is placed in a bath at 98° and the temperature is elevated as much as the patient will bear; immediately after the bath (which should last until the patient perspires freely), the patient is enveloped in woolen wraps and so remains for several hours." A free perspiration is kept up for several hours. The patient frequently regains consciousness before leaving the bath, others in the course of a few hours, whilst still others become tranquil and go into a natural sleep from which they awake in a day or two conscious. If labor has not begun, it should not be urged, as in many cases eclampsia has preceded labor, coming on a month or so in advance of full term, and if the convulsions can be cut short and the albuminuria cured the patient may go to full term safely.

Dr. Brens, in the *Archiv. für Gynäk.* (as quoted in the MED. AND SURG. REPORTER, vol. xlviii, p. 328), believes that active diaphoresis alone, induced by a hot bath (40 to 45° Cent.) followed by the pack, is sufficient. The bath must not be prolonged over one-half hour, and two or three hours is sufficient for the envelopment in the pack. This treatment, according to Brens, will also cause the œdema and albuminuria to disappear without interrupting the pregnancy.

I have never been situated so as to give the foregoing plan of treatment a trial, yet it commends itself to my judgment as being the only treatment that promises good results in those desperate cases of coma, either apoplectic or hydræmic. Even when we cannot use the bath, a pack, with the patient surrounded with bottles or jugs of hot water, might, I think, be tried with at least a hope of procuring an abundant perspiration and thus relieving the albuminuria without interrupting the process of parturition, if it be going on; or labor may be brought on prematurely, in the hope of emptying the womb as a means of relieving the kidneys.

Jaborandi and its alkaloid, pilocarpine, have been by many considered as the foremost of all remedies for the removal of albuminuria, and the control of the convulsions. Where it has succeeded at all it has done so by its powerful diaphoretic action, and as a substitute for the bath and pack beforementioned. It is to my mind a most dangerous substitute, however; for, while it is capable of producing the needed diaphoresis, it also is liable to bring on a most dangerous bronchorrhœa which, so far as I know, is uncontrollable. Whilst unloading the blood by cutaneous transpiration, it is filling the lungs and bronchi with a viscid mucus, which the comatose patient is unable to expectorate. Dr. Fordyce Barker gave jaborandi a fair trial in six cases: *all died.* Dr. Barker does not use jaborandi now, I believe. The medical journals a few years ago were teeming with the cures made by the use of pilocarpin; but like many other new things, it seems to be passing into oblivion—and very justly too, I think. There are many more deaths than cures reported under the use of this potent medicine.

Chloral hydrate should hold a conspicuous place as a remedy in puerperal eclampsia. In large doses, dissolved in mucilage or starch-water, and injected into the bowels, it has been sufficient to keep off the convulsions.

Bromide of potash or of soda, in large doses (30 to 60 grains), combined with aconite, veratrum, or gelsemium, as indicated, is always in order.

There are many other remedies, and expe-

dients which may be resorted to in this malady; but there is no absolute specific for it. The important thing is to understand the specific indications and be governed accordingly.

I have seen and treated altogether nine cases of puerperal eclampsia. Four of them were my own cases. Two more fell into my hands by accident or in the absence of the family physician. The remaining three cases were in the hands of other physicians and I was in consultation. All of the nine cases had albuminuria, and all were œdematous except two.

INTRAPELVIC INJURY CORRECTED BY LAPAROTOMY.

BY N. F. SCHWARTZ, M.D.,
SHANESVILLE, OHIO.

On July 14, 1888, Ida N., 26 years old, unmarried, presented herself for examination and treatment. The patient gave the following history of her case, which I carefully recorded and from which the following is drawn. She has not enjoyed good health for about nine years, during which time she has been under medical treatment almost constantly, without deriving any permanent benefit.

The conditions for which she had been treated were various, all however relating to intrapelvic trouble. Her menstrual derangements have, according to her statement, been of every possible variety; for a long time no two menstrual fluxes have been alike. The patient complains of a feeling of great fatigue, which is intensified when she is in the erect position, or during even moderate exertion of any kind. Sleep is disturbed, and the appetite capricious, though she seems well nourished. She has constantly an indescribable pain in the left side of the pelvis, which at times becomes aggravated, and then she has pain in the back and groin.

The patient first menstruated late in her fourteenth year; menstruation continued easy and regular until the winter of her seventeenth year, when she had a fall, to which she refers the beginning of her present illness. The fall occurred in the following manner: She was carrying a heavy burden down a stone-stepped cellar-way, which was covered with ice; she slipped and, before finally falling, made vigorous efforts to recover her footing, during which she felt as if something had given way, causing her intense pain. She then fell on her left hip and lumbar region, striking with all her weight on a corner of a stone step. She was assisted to her room, and was confined to bed for some time, and from that time to the present there has been hardly a day that she has not had some painful reminder of the accident.

Physical examination yielded very doubtful results. The patient was generally well developed. The abdominal circumference measured twenty-eight inches. The most prominent part of the abdomen was about midway between the umbilicus and the left anterior superior spinous process of the ilium. Pressure over this point elicited some complaint; palpation and percussion yielded nothing of value. Digital examination *per vaginam* showed the uterus to be *in situ*, beyond which nothing was learned. Here, after careful interrogation and reinterrogation, I rested my examination; I was far from any conclusion as to the cause of the symptoms. I prescribed a cathartic, and requested the patient to call again on the 20th, which she did.

On July 20, the patient reported that her bowels had been freely moved by the cathartic. The abdominal circumference was found to be increased to thirty inches in the standing position; the prominence of the abdomen previously mentioned seemed more marked, and deep pressure upon this point communicated a peculiar sense to the touch; the spot remained tender, and all previous symptoms were present and intensified.

The symptoms were certainly so undefined that no opinion could be formed except that there was some intra-abdominal or pelvic trouble or some injury resulting from the fall many years before. No certain diagnosis was arrived at therefore, and of course my prognosis and therapeutics remained equally uncertain. I told the patient and her friends candidly of my inability to make a diagnosis, indicating time and its developments as the all important factor in clearing up the present uncertainties. I stated that, should the present conditions continue to grow worse with time, and destroy her comfort and usefulness, exploratory laparotomy alone would clear up the doubt, and lead to a recognition of her trouble, not omitting to lay before her the danger such a measure necessarily implied.

Several months were allowed to pass, during which some alterative and palliative measures were employed, without, however, checking the rapid increase of the abdominal circumference, nor failure of appetite

and painful sleepless nights. One menstrual discharge in this time was profuse and painless, another was scanty and painful.

At this juncture at my suggestion, a practitioner of large experience, who had treated the patient during her failing health, was called in consultation. The consultation, however, resulted in nothing beyond a possible elimination of cyst development, which, on account of the rapid increase in the circumference of the abdomen, was reasonably suspected. Soon after this a consultation was held with another practitioner, who had previously had the patient in charge. The abdominal circumference was now forty inches. This consultant, after a most careful examination, found it impossible to unravel satisfactorily the perplexities surrounding the diagnosis.

Desiring still further to temporize, we determined to test the value of electricity. I accordingly resorted to the galvanic current, employing for this purpose a Harris battery, applying one pole over the sacrum with the other over the greatest prominence of the abdomen, thus continuing the static current for about fifteen minutes, the current being as strong as could be borne. This caused her much suffering for many hours following its use, and she objected to its repetition vigorously—but finally yielded to its application a second time. It however had the same result as before, causing much pain, and she would not again permit its employment.

The patient now demanded whatever there might be in laparotomy for her, as she was miserable and practically useless, desiring even to brave the hazard of surgical measures than to undergo longer the disappointment of experimental therapeutics and live a useless existence. The gravity of exploratory section was fully made known to her and to her family; the risks even, possibly, overdrawn; she, however, nothing daunted, desired the operation, not alone to have her trouble recognized and corrected, but also to silence the slimy tongue of scandal which was already wagging against her; and she preferred even to die if necessary, in vindication of her character.

I now acquainted Dr. John Homans, of Boston, with some of the salient facts in the case, and he very promptly suggested "a clean antiseptic exploratory laparotomy" as the proper thing to do to clear up any doubt in the case. And having exhausted the resources of even experimental therapeutics without benefit, I deemed it a duty to operate.

Every precaution, to the minutest detail, for complete antisepsis was observed, omitting the spray; and my patient and family yielded an intelligent obedience to every demand made upon them in carrying out the necessary antiseptic precautions before the operation, as well as in excluding the crowd of curious visitors afterward.

The rules as laid down by Prof. William Goodell, in Pepper's System of Medicine," governed my course throughout. The operation was done in a second story room of a large farm-house, with the assistance of my student Dr. J. G. Stucky, who assumed charge of the case for the three days next succeeding the operation, remaining with the patient.

The incision was made in the linea alba and was about three inches in length. The abdominal walls were found thick, and the recti muscles pressed fully an inch to the right side. In the pelvic cavity there was found left lateral flexion of the uterus, enlargement of the Fallopian tube on the left side. The tube contained fluid, but was not distended. The ovary was in front and under the tube, and was enlarged to the size of a large English walnut. The ovarian ligament was found overlying the tube near the uterus, and its terminal extremity about half twisting the tube upon itself. The parts were held in these different positions by adhesions.

There evidently had been a laceration of the posterior portion of the broad ligament at the time the patient had the fall, many years before, which alone could render such a displacement of the ovary possible; and the fall at the same time caused the tube to be held in such unnatural position as to render it almost impervious. I will not here attempt to say how the conditions described could act as a cause of long years of distress in an otherwise healthy patient. Suffice it to say, the correction of these different malpositions has relieved the patient *entirely*, and, since the fourteenth day after the operation, she has resumed her part in performing domestic duties with an ease and comfort not possible in many years. She now menstruates regularly and without pain, though somewhat scantily.

The recovery from the operation was prompt and easy, unmarked by a single unfavorable symptom. The only anodyne used was opium in a few suppositories.

Remarks.—In performing this operation I unfortunately overreached the limitations fixed by some of my neighboring fellow practitioners, exploratory laparotomy; and

my operation, though as successful in its results as could be wished, is looked upon as a violation of a "time honored custom," and I am criticized for performing it out of season. I am also reminded that I "found no tumor"; and so, because I did not discover in my patient's abdomen a tumor as large as a prize pumpkin at a county fair, my undertaking is declared a failure, etc.

As general practitioners of medicine and surgery of the latter part of the nineteenth century, we are met at almost every turn by some new problem, and measures which for many years remained in the hands of specialists, powerful for good or equally potent for evil, are becoming proper for general practitioners. Their intelligent comprehension and proper use are necessary in meeting the growing demands of the present time.

To us the practical needs of humanity are best known, and the questions of the hour have become a part of each day's study; and upon their correct interpretation depends much of the happiness or woe of those placed in our care. Moreover, as the conservators of the lives and health of those in our care, our duties, under the explicit professional mandate, *to restore health and preserve life without hazard, when possible*, and, *at all hazards when necessary*, cannot be performed in a merely perfunctory way.

Eager haste in using dangerous resources should and will always be discountenanced by careful practitioners, but dogged prejudices against their use when necessary are also reprehensible. Exploratory section, though practised for many years by specialists, hospital staffs, and many surgeons of large cities, beyond these environments has hardly attained recognition, and remains relegated to the realm of *post-mortem* surgery.

In advocating or contemplating laparotomy as an available diagnostic measure in general practice, that healthy conservatism which should preside over all important surgical means placed in our hands for use, when necessary, should not be ignored. It is a double-edged weapon of undoubted keenness, and is to be used only when we are reasonably assured that the end will justify the means.

The gravity of the operation will, and should, always keep it out of the fascinating current of fashion which has brought valuable operations into undeserved disrepute; *e. g.*, Emmet's operation—an operation of undisputed merit—was practised by some surgeons to an extent bordering, if indeed not trespassing, on the ridiculous. Every woman who came under the care of these enthusiasts was found on examination to have one or more lacerations of the cervix uteri, and "must have an operation performed."

It is one of the great triumphs of modern surgery that general practitioners may now extend to those situated away from special skill the advantages of both exploratory laparotomy and ovariotomy, which were hitherto accessible to only a privileged few.

Abundant proof of the value and comparative safety of exploratory section, when it is done in accordance with the well-established rules of antisepsis, may be found in surgical literature of the present and past years; and yet there remain those who continue to refuse patients this means and will temporize until nature asserts her inexorable claims, when no time is lost to make an autopsy and *find the cause of death*, great pride being taken in exhibiting *post-mortem* trophies.

Another reason urged against the performance of exploratory laparotomy by some surgeons throughout country districts is the fear of criticism by an uneducated laity. Medical men must necessarily be their own missionaries; they alone are to blame if Voodooism and religious superstition continue to obtain among the persons with whom they have lived for any considerable time. Intelligent persons will naturally seek for information concerning the healing art, and its limitations, whilst the ignorant should be enlightened as to our powers—and who are more competent than we to do it?

It may be fairly maintained that the degree of intelligence of a community upon matters pertaining to the medical profession is a fair index of the qualifications of their medical advisers; therefore the plea of an ignorant laity is in a great measure only a reflection upon him who offers it. Public opinion cannot guide us in our choice of means when dealing with disease, but we should pilot public opinion in all matters of reform and progress within our profession.

Such a position alone can command the confidence of the people and lead them to accept eagerly and confidingly any measure, however hazardous, when it is required to supplement the strong hosts of the materia medica in the battle against disease and death.

—The Indiana State Medical Society will hold its next annual meeting on Wednesday, May 1, at Indianapolis.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, April 4, 1889.

The President, A. L. Loomis, M.D., in the Chair.

An oil portrait of Ex-President A. Jacobi, M.D., was presented to the Academy by Dr. August Caillé and some of his colleagues.

Dr. T. Gaillard Thomas read a paper on

Acute Mania and Melancholia, or Hypochondriasis, as Sequelæ of Gynecological Operations.

His object was to place on record what he thought must be rather a remarkable experience as to the occurrence of these conditions. He stated at the outset that he did not announce these alarming conditions as complications or necessarily as results of operative procedure, but merely as sequelæ which may or may not be dependent upon the operation; and he did not assert that operations for the relief of diseases of women are more likely to be followed by them than other operations.

The author related six cases which had come under his observation, four of which were cases of acute mania, and two of melancholia. In four of the six there was evidence of eccentricity even before the operation, and in two of the four cases it was quite marked at times. In all the six, except one, there were distinct prodromal symptoms following the operation and antedating by some days the formal outburst. In the other the symptoms of acute mania came on rather suddenly, and resulted fatally within thirty-six or forty hours. In none could he discover an hereditary tendency to insanity. Of the six, four died, one completely recovered, one was still in progress. In all excepting one the urinary secretion was carefully watched and examined, and in none did the kidneys appear to be factors in the mental state. In four of the cases no iodoform at all was used, so that in them there could be no question of iodoform poisoning as a factor. In the two remaining cases the little that was used was along the line of external abdominal sutures, where absorption was almost impossible. His long experience with septicæmia barred that out as a factor.

In addition to his six cases, Dr. Thomas was able to find recorded in medical literature but twenty others, which would seem to show great rarity of the condition. Before concluding, he propounded the following questions:

1. Were these twenty-six cases of mania and melancholia really due to the operations which immediately antedated them, or did they follow as mere coincident states? 2. Any great mental strain may be followed by mania; is it at all remarkable that in the vast number of gynecological operations performed in the last quarter of a century in Germany and America that twenty-six cases of this malady should have occurred? 3. If the mania which followed the operations in the twenty-six cases was the consequence of them, how in the future is the tendency to this accident to be avoided? 4. Are the operations in gynecology any more likely than other surgical procedures to disturb the condition of the mind?

Dr. J. B. Hunter opened the discussion. He does not think gynecological surgery is more liable to the accident than other surgery. The condition does not seem so rare, for at a meeting a few nights before the surgeons present all related similar experiences. He has himself seen several cases. He divided the cases into four classes: 1. Those in which the condition is due entirely to the operation; these are few. 2. Those in which there is predisposition to nervous development, the operation acting simply as a torch. 3. Those in which the patient is already the subject of nervous disease, which simply progresses after the operation. 4. Those in which there is drug poisoning, as by iodoform, bichloride of mercury, carbolic acid, etc. He also thought ether in some patients who had a predisposition might bring on insanity. A psychological condition should not interfere with the operation unless it was incipient insanity. Then the operation was justifiable in as much as it benefited psychological patients oftener than it brought on the condition described in the paper. Operations exposing a large surface might possibly tend more to the condition by offering a better opportunity for drug poisoning.

Dr. Nichols, Superintendent of the Bloomingdale Asylum, said only two cases of insanity following gynecological operations had been in the hospital in the past eleven years, one of which was in a patient of Dr. Thomas's. He thought long contemplation of an operation might place the mind in a favorable condition for insanity before or after the operation.

Dr. P. F. Mundé had had three cases of insanity following gynecological operations,

his first patient, seven or eight years ago, dying in a maniacal state. He then supposed it was due to septicemia, but is now convinced that it was not. Another case was one of melancholia, of recent date, showing itself partly in refusal to speak for three or four days after the operation. In the third case the operation was Alexander's, with antero- and postero-kolporraphy for prolapsus. The patient remained maniacal two weeks after the operation, and recovered. He does not believe iodoform has anything to do with the condition, for in some cases wounds were packed full of iodoform and mania did not follow.

Dr. W. M. Polk thought it was only to be expected that mental disturbances were more likely to occur in gynecological operations than others, or in women than in men, for the female sex is more emotional, and once a month many women who at other times show the best judgment and greatest business ability, are so irritable as to be incapable of managing ordinary domestic affairs. He much prefers not to operate on women who beforehand show any mental peculiarity or eccentricity, for he has had three cases of insanity following operations on such patients, all of the patients dying. One of his patients had a sister who also was peculiar.

Dr. W. Gill Wylie had had but one case of insanity following a gynecological operation, but he had operated on a number of patients who were already wholly or partly insane, sometimes with the result of curing the mental condition. The treatment of the rectum and colon which in such patients are often diseased has a markedly beneficial effect on the nervous disorder. His mind is not yet fully made up on the subject of the paper.

Dr. Townsend, of Albany, related a case in which salpingo-oöphorectomy was performed during the past winter on a woman who, about seven days after the operation, became markedly melancholic and hysterical, and went on to develop acute mania. She died comatose, apparently from exhaustion, as was true in most of Dr. Thomas's cases. This patient showed marked hydræmia before the operation.

Dr. Landon Carter Gray thought to Dr. Thomas belonged the credit of having described a new genus of insanity. His six cases corresponded to none of the described forms in all respects. They properly belong to delirium grave—most of the cases of which die—and to the form called post-febrile insanity. He would distinguish it as post-operative insanity, rather than as acute mania or melancholia following gynecological operations.

The President mentioned a case of his in which Dr. Lange removed one kidney, the operation being followed some days later by acute mania, from which the patient finally recovered and still remains perfectly well.

Dr. Thomas, in closing the discussion, referred to some of the side questions which had been raised, among others that of iodoform poisoning, and said it was a serious question whether or not, if iodoform were capable of producing such grave symptoms as had been described, its use were justifiable at all. As to ether producing insanity, he thought from long experience that it was impossible, yet he had had such disagreeable results from its use after laparotomies, in the form of prolonged vomiting, etc., that he thought it a serious question whether American surgeons would not do well to abandon its use for that of chloroform in abdominal surgery. Regarding the influence on the patient's mind of long contemplation of the knife, he thought it was marked, and for that reason he advised his students always to remove tumors of the breast, of whatever nature and whatever size. It would do no harm. It might prevent cancer. It certainly would relieve the woman's mind. He left it for others to answer the questions which he had propounded.

—The committee appointed to investigate the discovery of M. Pasteur for the extermination of rabbits in Australia has made a report of the result of their inquiries, which states that upon experiment it has been found that rabbits which had been inoculated with the virus of chicken cholera, or which ate food which had been infected with the virus, died, but that the disease was not communicated by one rabbit to another.

—The *New York Tribune*, March 26, 1889, says that F. W. R. Waring, who has practised medicine under the name of "Dr. Thomas McGahan," was sentenced March 25 by Judge Cowing to five years in the New York State Prison for violating provisions of the Medical Code of New York State. The sentence is the most severe that has been passed under the code, but the defendant had been indicted for manslaughter in causing the death of a woman several years ago, and was twice tried on the charge.

Reports of Clinics.

PHILADELPHIA HOSPITAL.

CLINIC UPON OBSTETRICS—DR. PARVIN.

Inflammation of the Breast After Death of the Infant.

The first patient presented at Dr. Parvin's clinic, on February 27, was a woman, twenty-five years old, who more than three weeks ago had given birth to a child that died three days subsequently; a few days afterward inflammation of the breast was observed. There was a chill, and some continuous elevation of temperature succeeded it. The inflammation had extended so that suppuration seemed inevitable, notwithstanding that ice had been used, and then compression of the diseased gland with a bandage, the internal employment of quinine and of salines. Referring to this case Dr. Parvin said: Mammary inflammation occurs, according to Winckel's statistics, in about 6 per cent. of all lying-in women, and the vast majority of those thus affected are primiparæ. The disease appears most frequently in the second or third week of lactation; it usually begins with a chill, which is succeeded by fever, and, according to Schroeder, if the fever continues to the third day suppuration is almost inevitable. It has generally been held that the disease is in most cases a lymphangitis, and has its origin in disease of the nipple, such as fissures and excoriations, the infecting agent entering through these breaches of tissue. But now it seems to be well established that the infection may find its way not only through these wounds and the lymphatics, but also through the milk canals, for bacteria have been found in the milk in the yet undiseased gland. An interesting fact may here be stated, that these bacteria have the power of changing the normal alkalinity of the milk, and this fluid becomes acid: it would be well if the Resident having charge of this patient, would ascertain whether the statement can be verified in her case—that is, as to the milk having become acid. The staphylococcus is the one most frequently found in lobular inflammation; Cohn discovered in a non-suppurating parenchymatous mastitis a peculiar streptococcus. Further, it has been shown that in phlegmonous mastitis the streptococcus pyogenes is present. These facts as to the different bacteria present in mammary inflammation, are briefly presented in the last edition of Schroeder's work upon obstetrics.

Two remarkable things are to be noticed in this case. First, the inflammation occurred without any previous disease of the nipple, at least none was observed. Next, the little elevation of temperature the patient has had—it has seldom risen above 100°, F. Now the first fact can be explained only by admitting the hypothesis that the infection entered through a milk duct, and this view is further sustained by the statement that the inflammation began in one of the lobes of the gland. A question of some practical importance is, what effect if any has arrest of lactation upon inflammation of the gland; or, in other words, will the retention of milk be injurious? In the great majority of cases this question may be answered in the negative. Winckel makes the statement almost in this form; and he adds that he has never seen sudden interruption of lactation the cause of mastitis. So positive was I, indeed, in reference to this point that my axiom for many years was, milk does not make matter. It may, however, be now stated that in some cases it is possible that the entrance of microörganisms through the milk ducts into the milk may produce such changes in the milk that mastitis results.

In the treatment of mammary inflammation as you meet it in the nursing woman, the first thing is to take the child from the breast; next properly support the organ, and probably give a saline. Then you will consider the two methods which, as you know, have been vainly tried in this case—ice, and the compressing bandage. A few years ago a physician living near Philadelphia, whom all men honor for his many years, his faithful labors, and his useful life, Dr. Hiram Corson, wrote a paper strongly advocating the use of ice, stating that he had always had favorable results in mammary inflammation when the remedy was employed soon enough. Then again the bandage has been just as strongly advocated by others. And I must say that between the two my preference is for the latter. Schroeder recommends the ice treatment only in case the inflammation is superficial. But my preference may be a mistake; there are many things in medicine in regard to which we had better say, we believe, rather than we know. We are so eager for certainties that there is something very fascinating in positive utterances, in the declaration of what is claimed to be absolute truth, in dogmatisms. And here, without any reference to

the therapeutic views which have been presented, but speaking in general, it seems to me that there is no class of men who need to have impressed upon their minds more strongly that one swallow does not make a summer, than young physicians and medical students. How often one hears physicians who have lived for some years veiled in their own vanity, and with very limited knowledge, endeavoring to set aside truths established by large inductions, because their experience is different. A man who imagines that the feeble light of his "tallow-dip" will reveal to him such vast knowledge that he need not care what others have discovered, and that he is in a position to contradict their discoveries, is one of the most dangerous of human beings, and at the same time he is one of the most useless in his vain boasting and self-glorification.

Returning to the treatment of this patient, I do not think any further continuance of the quinine is indicated, the elevation of temperature is so slight; the saline may be still used, and so too the bandage will be applied, for it gives the patient comfort; but it will hardly prevent the formation of an abscess.

Before leaving the subject of mammary inflammation, let me refer to a form of the disease which occupies only a superficial portion of the gland, and the presence of which does not require taking the child from the breast. This has been called sub-areolar inflammation; a tumor as large as a filbert, as a hickory nut, or even as a walnut appears, is sensitive, though not exceedingly painful, and soon suppurates: free exit for the pus being made rapid healing follows. This superficial mastitis need not interfere with nursing. In the graver forms of suppurative mastitis an early opening should be made, all antiseptic precautions being used, and a drainage tube inserted. In regard to the gravest form of mastitis, that which occurs as one of the manifestations of general septic infection, rare even in such infection—which itself is not frequent and is becoming still less so with the advent of physicians who believe in antiseptic obstetrics—I shall not speak to-day.

Striæ upon the Abdomen, the Hips, and Mammæ.

This woman is presented before you that you may see an unusually striking instance of the striæ gravidarum, which in her not only occupy two thirds of the anterior abdominal wall, but are also found upon the hips, and especially upon the mammary glands. She is now seven months advanced in her pregnancy, and the abdomen seems very greatly distended, though there is no reason for believing there is either plural pregnancy or polyhydramnios. Having in a previous lecture considered at some length the origin and significance of the striæ of pregnancy, I shall not speak of these topics to-day.

Pulmonary Tuberculosis and Pregnancy.

Two weeks ago there was brought before you a primigravida, seven months pregnant, who had tuberculosis, the disease involving both lungs. She had been married less than a year, and, a little before she became pregnant, as she said, "caught cold," and ever since has been losing flesh and strength. A few days ago this woman had premature labor, and her child died; the disease has been making rapid progress since, so that her death may occur almost any day. The case illustrates what you will too often be called to witness, the usually injurious influence of pregnancy upon so-called consumption; or if there is a temporary improvement while the woman carries her child, the labor is frequently followed by a more rapid progress of the disease. In many cases the pregnancy does not go to term, miscarriage or premature labor occurring: these accidents in some instances result from the violent coughing, in others from the death of the fœtus, and in still others possibly from the imperfect aeration of the blood, that is, accumulation of carbonic acid excites uterine contractility. The teaching when I was a medical student was different from that which I believe it my duty to give you; how well I remember that most courtly gentleman, that accomplished teacher and learned physician, the late Dr. George B. Wood, telling us that he had in many instances seen the disease kept at bay in women by marriage and childbearing. The investigations of the late Dr. Austin Flint have shown, on the other hand, that in a large proportion of women pregnancy and lactation are important factors in the development of the disease. Therefore it is best, so far as the woman herself is concerned who already has pulmonary tuberculosis, or has any decided tendency to such disease, not to marry; and if married it is fortunate for her if she do not become pregnant. Even if she escape the death penalty, she can not expect to bring into the world healthy children. Marriage is no more an infirmary

for consumptive women than it is a reformatory for debauched and drunken men.

A Case of Justo-Minor Pelvis.

The patient now lying upon the table is said to have a justo-minor pelvis, that is, a pelvis which, theoretically at least, has all its diameters uniformly lessened. But, that you may properly appreciate the fact, her pelvis will be measured before you, and the measurements obtained contrasted with those of the normal pelvis, putting the two side by side upon the black-board.

The distance between the anterior superior spinous processes of the ilium are in this pelvis,

Twenty-four centimeters. In the normal pelvis, 25. Between the iliac crests, 25c. In the normal, 28c. The external conjugate is 19.5c. In the normal, 20c. Distance between the trochanters is 28c. In the normal 31c. The circumference of the pelvis is 83c. In the normal 90c.

But in order to complete the pelvimetry we should have the diagonal conjugate, by deducting 2 centimeters from which we have, in most cases pretty accurately, the true conjugate. In an effort to ascertain the diagonal conjugate it was difficult to reach the promontory, and in such case the usually just conclusion is that the true conjugate is not materially shortened. Still more, the measurements of the pelvic outlet must also be obtained before we can conclude that the pelvis presents all the characters required in the term justo-minor. But it is not necessary to carry this examination further, for while all the measurements made are less than the normal, yet the differences are not great, and it is quite probable that the labor will not require any aid from art.

Nevertheless a word or two upon labor and its management in the justo-minor pelvis. The descent of the head into the pelvic cavity, which occurs in the great majority of cases of primigravidæ in the latter weeks of pregnancy, is not observed, and labor begins with the head at the inlet; strong flexion is necessary to secure its entrance, and such flexion is the rule during the entire passage through the pelvis. The labor is longer than in the case of a woman with a normal pelvis, and the caput succedaneum of unusual size. Nevertheless you would not think of trying to shorten the labor before the head had been very completely moulded, by the application of the forceps. Further, you would regard it as fortunate that the vertex presented rather than the pelvis, for the delay in the passage of the head would in the latter case be so great that the child's life must be lost almost inevitably. It is hardly necessary to add after this statement, that podalic version is contra-indicated in the justo-minor pelvis.

An interesting fact in the history of this patient is, she had typhoid fever a few weeks ago, but as you see the pregnancy was not interrupted, nor was there any threatening of miscarriage during the illness. It has been claimed by some authorities that pregnancy in a good degree exempts women from typhoid fever; but such an opinion is not generally held. Very frequently the pregnancy is arrested by the disease—according to some statistics in more than one half the cases; but it is probable that these statistics are derived chiefly from hospitals in which cases of especial gravity are found, and that if we were to collect from a large number of physicians in private practice their results, the conclusion would be different. This opinion is based upon the fact that I so frequently read in medical journals, or hear reported in medical societies, cases of typhoid fever in pregnancy, and the latter pursuing its normal course. Various explanations of the death of the fœtus and the consequent interruption of the pregnancy, have been given. One of these is that the high maternal temperature (the fœtal as you know being greater normally than that of the mother) brings danger and death to the fœtus. This conclusion was drawn from experiments upon pregnant animals, in which miscarriage was caused by subjection to very high temperature. But experiments made subsequently proved that if the elevation of temperature was gradual this result did not follow, but the pregnancy continued. Probably the most frequent cause of miscarriage or premature labor in the pregnant woman suffering from typhoid fever is hemorrhagic endometritis.

Accidental Hemorrhage.

If hemorrhage occurs in a pregnant woman, the placenta occupying its normal situation, the hemorrhage is called accidental. Recently one of the women, in the waiting-ward, quite far advanced in pregnancy, went out to visit some friends; the night after this visit she had severe hemorrhage, losing according to the statement of the Resident at least a quart of blood. There were bruises upon the abdomen, but the woman would not acknowledge that she had met with accidental or intentional injury. The treatment employed was successful in stopping the bleeding, and the chief part of

that treatment was thorough tamponing of the vagina. After her recovery it was impossible to hear the sounds of the fœtal heart; her pregnancy, however, went to term, when she was delivered of a dead child, the death having occurred at least several days before. The failure to hear the fœtal heart sounds in several trials, after having previously heard them distinctly, is quite conclusive evidence that the child is dead. Recently a new proof of the death of the fœtus has been brought forward, and this is the presence of peptones in the urine of the mother—that is, she has peptonuria. Now if a sufficient number of observations come to confirm this statement, the fact will be one of very great value, so that we will not need stethoscopic examinations to decide as to the death of the fœtus. Unfortunately this method of examination was not suggested in the case considered.

A word or two in regard to the treatment of accidental hemorrhage. The admirable paper by Dr. Goodell upon this subject, which was published some years ago, is a fountain of knowledge from which all who ever write upon accidental hemorrhage necessarily draw; it proved how very dangerous this occurrence is to both mother and child. Yet I think that possibly those who advocate immediately emptying the uterus, as most obstetricians do, as the essential thing in the treatment of accidental hemorrhage, are too positive, too absolute in opinion, too active in practice. This case which has been narrated to you illustrates the fact that by the tampon the danger was averted so far as the mother was concerned—it is probable no treatment would have saved the child. Spiegelberg and others, who have opposed immediate delivery, take the ground that with the unruptured membranes you have most effective pressure for the arrest of the bleeding; when those membranes are ruptured and the amnial liquor escapes, unless vigorous uterine contractions follow promptly, hemorrhage is invited, not restrained. Thus you will see that this is not as simple a question with only a single answer possible, as some think. There are comparatively few things, in obstetric therapeutics at least, in regard to which you may positively say, "This, and this only, is true."

I think that the course pursued in the case presented was wise, and the immediate induction of labor would have been most perilous to the mother: therefore the action of the resident physician is to be commended.

PERISCOPE.

When to Interfere in Acute Intestinal Obstruction.

At the meeting of the Medical Society of London, Feb. 18, 1889, Dr. B. W. Richardson read a paper with the object of eliciting an expression of opinion as to the proper moment for resorting to surgical interference in cases of intestinal obstruction. He confined his remarks to acute attacks, leaving aside all cases of the chronic kind, from malignant stricture or hernia. He narrated a typical case which he said might serve as the base of his observations. The patient was a man who had gone to bed in apparent good health, but was awakened during the night by violent pain in his abdomen, and special symptoms pointing to mechanical obstruction high up. He was called to the case by Mr. Buckston Browne. Purgatives had been tried without effect, and a long tube was passed into the bowel and an injection used, but without affording any relief. There was no fever, but the conjunctivæ were tinged slightly yellow. There was an obscure history of gall-stones some years before. On making a careful examination of the abdomen, a well-defined hard substance could be felt in a line with the transverse colon, movable laterally but not in any other direction. They arrived at a diagnosis of obstruction caused by impacted gall-stone. The patient complained of nausea, but there was no vomiting. They injected a copious enema of oil, and soon after a fair-sized gall-stone passed from the rectum. This was followed by immediate relief, but some hours later the pain returned, and then there was vomiting with a fecal odor. They determined to try another injection of oil, and other mild measures, and to operate in the morning if relief was not obtained. During the night the symptoms recurred with such violence that the patient rapidly passed into a condition of collapse, and died before anything could be done. At the *post-mortem* examination they tried what could have been done by operation, and they found that they could easily have come upon a calculus fixed in the lower part of the small intestine, a little above the cæcum. This could have been pushed along the gut and extracted without difficulty and without opening the intestine. Three other small calculi were found in the colon, and at the entrance to the common bile-duct there was some ulceration and adhesion, together with an abscess

of the substance of the pancreas. He discussed the nature of the case and the chances that early operative interference would have been followed by relief to the symptoms. He summarized his conclusions as follows: 1. That in all cases of acute intestinal obstruction the use of milder measures, such as purgatives, enemata, massage, etc., may safely be carried out until the supervention of fecal vomiting. 2. That as soon as this is established an exploratory incision into the abdomen should be made without delay. 3. That obscurity of diagnosis, in the presence of this symptom, should not be allowed to stand in the way of an operation. 4. That clinical experience shows that there is very little chance of recovery, when once stercoraceous vomiting has declared itself, unless an operation is performed. 5. That fecal vomiting is a symptom of much more gravity than would attach to the mere mechanical effect of obstruction. 6. That symptoms of collapse are not a contra-indication to operative interference.

Mr. Edmund Owen observed, in regard to the question as to when to operate in acute intestinal obstruction, that some men would say, when the physician has done his best or his worst; as a general rule the surgeon is called in too late. He urged that the symptom proposed by Dr. Richardson as the test would not be applicable to a large class of cases in which the obstruction is high up, say in the jejunum. In such cases fecal vomiting can not take place, and if the patient is allowed to go on while they wait for that sign, his chances of recovery will be few.

Mr. Bryant urged that surgeons should be guided less by this or that sign than by the diagnosis of the particular nature of the strangulation. He objected to the term obstruction, as applying only to the cases in which the difficulty came from the inside, by far the least frequent source of mischief. In any case he thought that much valuable time would be lost if the advent of fecal vomiting were awaited; by that time a great deal of the mischief is done. He said that directly the surgeon was satisfied that there were symptoms of strangulation he should be prepared to operate.

Dr. Ruth protested against too speedy a resort to operative procedures. He said he had met with a great many cases in which recovery had ensued without operation, although stercoraceous vomiting had occurred. He advocated a freer use of antispasmodics, such as chloroform and belladonna.

Dr. Richardson, in reply, admitted that he had not mentioned the cases of obstruction high up. Such cases are very rare. He prefers the term obstruction as more comprehensive than strangulation. He doubts the ability of the surgeon to arrive at a differential diagnosis in a large proportion of the cases, and fecal vomiting is generally the first sign to impress the medical attendant with a sense of the gravity of the case. If the plan suggested by Dr. Ruth were confided in, the patients would often die, for want of more radical measures.—*British Med. Journal*, Feb. 23, 1889.

Symmetrical Gangrene.

In the *Medical Chronicle*, Feb., 1889, Joseph Collier reports a case of symmetrical gangrene, or Raynaud's disease, occurring in a single woman, 20 years old. After giving a full account of the case and of the results of the autopsy, he says that from the point of view of causation, the disease seems to fall into one of several groups:

1. Those due to a direct stimulation of the peripheric ganglia. In this group are the cases with gangrene dependent on vascular spasm, produced by some altered condition of the blood. Of course in these cases the production of gangrene will be partly due to mal-nutrition of tissue, and partly to action of the blood on the higher cerebro-spinal centres, as in cases of paroxysmal hemoglobinuria.

The gangrene of Bright's disease, and of diabetes mellitus, will be to some extent produced in this manner. The vaso-motor symptoms in alcoholic paralysis are probably also due to the circulation of impure blood.

2. Those due to irritation of prevertebral sympathetic ganglia, or vaso-motor nerves leaving them, as in the author's own case.

Probably pathological conditions of the large abdominal sympathetic ganglia are much commoner than is usually suspected, especially in anemic girls of the age of those generally attacked by Raynaud's disease. Dr. Donald has pointed out to Mr. Collier as an interesting fact in this connection, the frequency with which epigastric pain in anemic girls is associated with pulsating aorta, and a form of constipation due partly to anemia and partly, no doubt, to splanchnic spasm. Many vaso-motor fibres accompany the spinal nerves, and thus in those cases in which gangrene from neuritis approaches the paroxysmal form, it will be to some extent due to action of these fibres.

3. Those due to irritation of central origin, as in a case of gangrene of the

left hand recorded by Hochenegg, in which chronic hydrocephalus and syringomyelia were found at the autopsy. Cases more or less due to emotional origin would come into this group.

4. Those due to some peripheral stimulation acting reflexly through cerebro-spinal centres. Thus, cutaneous sensory fibres irritated by cold, or in the cases of symmetrical gangrene from scleroderma. Here again part of the action of peripheral neuritis in producing arterial spasm will be produced in this manner. In the cases of the disease associated with syphilis, congenital or acquired, it is difficult to be positive that endocarditis, or some other arterial degeneration, has not been the main cause.

Case of Cerebellar Abscess.

Dr. George Buchan communicates an account of a case of abscess of the cerebellum in the *Glasgow Medical Journal*, Feb. 1889. The patient was a woman, a mill-worker, 63 years old, and was admitted into the Town's Hospital on May 15, 1888. She was a very healthy woman, and never had any very serious complaints, and was always at work until the illness to be described began.

About a week after New Year's she began to complain of symptoms resembling a severe coryza, but only on one side of the head, the right. There was running at the nose (right nostril), watering of the right eye, and at times an involuntary winking of the right eyelids. This continued for about a week, when a severe pain began in the right occipital region, which gradually extended all over the right side of the scalp and stopped at the right eye. The pain was not continuous, but came and went. A fortnight later she began to vomit occasionally a very bitter green stuff, which she thought was the bile, and at same time began to feel at times a giddiness in the head, and was languid and tired about her legs; to assist her when she was coming home from her work she would get between two of her fellow-workers, and, placing an arm in each, was thus steadied and helped very materially in the getting home. On account of the vomiting she consulted physicians, who prescribed for biliousness. The patient continued in this state for about a month or six weeks, still at work, but tired, languid, and feeble about the legs, with a sensation of swimming in the head, and always liable to fall; in the house, if she was bending down for anything, she would fall down altogether, and she got many a fall that way. She then had to take to her bed. She was restless in bed—one time at the head and another time at the foot of the bed; she also became very irritable in her temper, and her niece could not put up with her any longer. She applied to the Parochial Board, when she was visited by the district doctor, who said the trouble was nervous debility, and ordered her removal to the hospital.

On examination in the hospital she was found to be fat and well nourished, lungs and heart normal, abdominal organs normal, no albumin in the urine, and the quantity of urine normal. She complained of diarrhœa and slight vomiting; and on examination it was found that the stools were loose, but the bowels were not frequently moved. The tongue was clean; there was no nausea; and the vomiting, even in the worst attacks, occurred quite mechanically. She took her food fairly well, but as a rule for some time after her admission she vomited always a little of the food. On looking at her face, there was a peculiar leer about the right eye, which reminded Dr. Buchan of the look of one trying to make fun of another. Pupils were regular and responsive to light, and there was no complaint about her eyesight; she could see as well as ever she did; her hearing also was quite good, and there was no history of her ever having had suppurating ears. There was no paralysis anywhere; the reflexes were normal. In bed she lay principally on her right side with her legs drawn up, her head drawn a little backward and to the right, boring into the pillow. She could turn herself any way, and draw up and put down her legs. On being assisted out of her bed and asked to walk along the floor, she could do so as long as she was holding on by the bed, but no farther. Dr. Buchan on the one side and the nurse on the other tried to help her along, but she was just like one miraculously drunk. She tried to steady herself but could not—her legs bent under, her feet slid away from her. Thus reeling backward and forward, she would have fallen backward and to the right had she not been kept up. By a process of exclusion he came to the opinion that this case was one of cerebellar disease, as the characteristic symptoms of this lesion—staggering gait, vomiting, giddiness, drawing back of the head, and to the right in this case, and severe occipital pain—were present. The pain, however, was not at the seat of lesion, as some authorities state, but at the opposite side. The patient continued in this state quite happy and con-

tented and taking her food well, when about three weeks before death she began to complain of a numb feeling in her lip and arms, her speech became thick, and there was a slight difficulty in swallowing. This continued for a week, when paralysis of the lip and arms set in, and she could no longer feed herself. There were no rigors or sweatings at any time. Four days after this the temperature rose a little (99.6°), and paralysis of the sphincters set in, and two days before death there was stupor and coma.

At the autopsy the membranes of the brain were found fairly healthy, with here and there evidences of old slight inflammatory adhesions between the dura mater and the arachnoid. The left lobe of the cerebellum had a soft, pulpy feel, and on turning upward the base of the brain, there were found five or six openings on the posterior inferior lobule of the cerebellum, out of which a yellowish, glairy fluid was oozing. Dr. Buchan describes it as having just the appearance of a discharging carbuncle before the slough separates. On cutting two or three of the divisions and tearing up the part, a ruptured encapsuled cavity was displayed, as large as a medium sized egg. This ruptured cavity explains the symptoms noted thirty-six hours before death.

Hernia of the Parturient Uterus Through the Linea Alba.

In a paper read before the Medical Society of the District of Columbia, October 31, 1888, Dr. Charles E. Hagner said that in July, 1884, he delivered a primipara, after a prolonged labor, of a full-term female child. Forceps were used, with slight laceration of the perineum, which was immediately stitched up and healed perfectly. The patient made a good recovery, and showed no signs of ventral hernia. In March, 1886, Mrs. B. was delivered of a second full-term female infant without forceps, the perineum remaining intact, the labor being a short one (six hours), and perfectly normal. Within three months the patient called his attention to a "lump" about the umbilicus. Upon examination he found an umbilical intestinal hernia, about the size of an egg, which was readily reduced, the opening being large enough to permit the introduction of the end of the finger. An abdominal truss was ordered which retained it perfectly. The patient wore this until she was taken in labor with her third child, in Feb. 1888.

On Feb. 8, 1888, he was called to see Mrs. B., and found her in the first stage of labor, the os dilating and the pains frequent. He remained an hour, when, everything progressing normally, he left her for an hour and a half. Upon his return he found the bag of waters ruptured, the patient in bed and in active labor; the os fully dilated, the head engaging L. O. A. The labor progressed normally and actively for about an hour and a half, examinations being made from time to time. Suddenly the patient, after a very violent pain, called out and said: "Oh doctor, I am tired out, I can no longer bear down." It had been about ten minutes since Dr. Hagner's last examination. On approaching the bed, he observed that the abdominal tumor, heretofore perfectly normal, presented a peculiar appearance, being much more prominent, and seeming to project at right angles to the patient's body, who was lying on her back. Upon lifting the sheet, he was startled to find that the uterus had left the abdominal cavity, and was covered only by the skin, which was very tightly stretched, and seemed as thin as tissue paper. The uterine vessels were clearly seen, also the contractions, when a pain came on. The head at this time was in the vagina, and he immediately saw that the woman was correct in saying that she could make no expulsive effort. Notwithstanding the uterine contractions, which were regular and strong and visible, the head made no advance, and the patient becoming exhausted, Dr. Hagner immediately applied the forceps and delivered the child. There was no difficulty in applying the forceps, as the head was well down, but the impossibility of restoring the uterus to its normal position, and its tendency to fall to one side or the other, made it necessary to have the nurse support it in the median line until the child was extracted. It proved to be another fine healthy girl. The placenta was quickly extracted by the hand, as the patient seemed exhausted, and Dr. Hagner was most anxious to terminate the labor.

As soon as the placenta was removed there was little trouble in replacing the uterus through the opening in the walls of the abdomen, it having thoroughly contracted and reached its proper size. A suitable bandage was applied, and the woman made a good recovery. It is surprising, he says, to find how small an opening there seems to be in the abdominal wall at present. The woman is wearing the abdominal bandage she wore before her last pregnancy, and says she suffers no inconvenience.—*Jour. of Amer. Med. Association*, March 2, 1889.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE STATE BOARD OF MEDICAL EXAMINERS.

Since our last Editorial in regard to the proposed law to establish a State Board of Medical Examiners in Pennsylvania, the bill before the House of Representatives has been amended by adding a proviso that at no time shall a majority of the members of the Board belong to any one school of medicine. This proviso has been inserted on the recommendation of the homœopaths, who protest that if the old school were in possession of a controlling power in the Board it would sooner or later use it to oppress practitioners belonging to other schools. This fear is not unnatural, although we believe it to be unwarranted. Our hope has been that the establishment of a State Board of Medical Examiners would tend to obliterate the distinction between those who practise according to the dictates of common sense and sound reasoning, whether they are openly attached to the school which holds this to be the only proper method or are called by a name which implies that they follow some other and more restricted one. In this way, we have hoped—and see no reason to conceal the fact—that before long the title of physician would come to be sufficient for all who practise medicine, and that medical schools would have no other ambition than to teach their students thoroughly the nature and effects of disease and the means which experience has shown to be the best for curing it. In regard to these points men have differed in all ages, and it may be long before the wisest are of one mind; so that there is room for honest variance in theory and in practice, and there ought to be tolerance between those who differ, while yet all are pressing forward toward the same goal. Of oppression there ought to be no question, and we regret that the homœopaths have so little confidence in the sincerity and fairness of those who make up the overwhelming majority of the medical profession.

At the same time we are so convinced of the desirability of having the right of licensing men to practise medicine taken from the medical schools, that we would rather have a Board constituted after a concession to the unreasonable fear of the minority than no Board at all, and we feel sure that the result of its operations would be to secure for our fellow-citizens a better class of physicians than can be secured so long as each medical school may fix the grade of attainments for its own graduates and have its diploma stand as well before the law as that of any other.

So far, then, as the amendment referred to

is concerned, we trust that it may not prove an obstacle to the passage of the proposed law in Pennsylvania.

Another amendment has been proposed by the active supporters of the bill, which is intended to make it more beneficial to the community. This amendment requires that those who apply for a license to practise shall have passed through a four years' course of study in a chartered medical school. The effect of this amendment would be to compel all the schools in this State to adopt a four years' course, and to incite all the schools in the Eastern States to do the same, as otherwise their graduates would be disqualified for practising in Pennsylvania.

If this amendment be adopted it ought to be developed, so as to define what a year of study is to mean. Without such a development it might soon prove a farce.

CONFERENCE ON YELLOW FEVER IN FLORIDA.

The epidemic of yellow fever in Jacksonville, Florida, last year impressed upon the State the necessity for the creation of a State Board of Health, and one was called into existence, too late to be of service in that epidemic but with the hope that its counsel might aid the citizens and physicians of the State in the attempt to prevent a repetition of the sad experiences they had recently passed through. The State Legislature at its last session adopted a resolution inviting a commission of sanitary officials to visit Jacksonville and other points in Florida exposed to outbreaks of yellow fever, and to confer with the State Board of Health as to the best means to prevent a recurrence of the epidemics of previous years. In response to this invitation, a number of gentlemen, representing the sanitary authorities of different sections of the country, started from Washington April 1, and the result of their mission will be looked for with much interest.

It is to be hoped that the visitors will succeed in giving the aid, by counsel and moral support, which is looked for by the newly created State Board of Health in Florida. If they make a careful inspection of Jacksonville, and if they confer with men who feel that it is better to heal a sore than to clap a plaster on it and say it is well, they will undoubtedly find opportunity to make suggestions which that city might wisely adopt. At the present time it is in a condition which falls far short of the standard of cleanliness which prudence dictates, and its sanitary arrangements are by no means what they ought to be. These matters will no doubt attract the attention of the visiting sanitarians, to whom a rare opportunity for useful work is open.

It is to be hoped that this year no serious outbreak of yellow fever will occur in the South; and, if it does, we hope that its management will not be in the hands of men whose recommendations reflect the ignorance and senseless fear of the middle ages. Cleanliness, calmness and intelligent views as to the nature of yellow fever would banish it almost wholly from the Florida peninsula; and we trust the conference which has just taken place, and the cöoperation which will doubtless follow it will contribute materially toward the attainment of these conditions in regions where yellow fever has heretofore occurred.

DENTAL FISTULÆ.

The recent report by the *Deutsche Monatschrift für Zahnheilkunde*, December, 1888, of a remarkable case of dental fistula, in which an opening near the nipple of the left breast was found to be caused by disease of the roots of the first left lower molar tooth, furnishes an illustration of the importance of bearing in mind the possibility that disease of the teeth may manifest itself in comparatively remote lesions. One who is sufficiently impressed with this fact may often find a way to cure sinuses or fistulæ which otherwise would baffle treatment.

It ought to be a rule with physicians and surgeons to examine the teeth of their patients whenever there is the slightest reason to believe that they may be a cause of obscure disorders. This rule applies obviously to fistulous openings upon or near the face; and the case cited shows that what seems an almost incredible distance may be traversed by the products of a diseased tooth. It also applies to other disorders, such as neuralgia, and affections of the ear, which are not infrequently dependent upon disease of the teeth. Various specialists have called attention to this matter at different times; but there is still some propriety in directing the attention of general practitioners to it, and in suggesting to them that they may often find an educated dentist a valuable colleague in the management of their patients.

LABOR IN WOMEN WITH FLAT PELVES.

The disputed question as to whether it is best in cases of labor complicated by minor degrees of flattening of the pelvis—in which the natural forces are incompetent to effect delivery—to render assistance with the forceps or by version, is still awaiting authoritative settlement. The impossibility or undesirability of applying the forceps to the sides of the head when it is arrested at the brim in the flattened pelvis, on the one hand, and on the other the fear that by applying them to the sides of the pelvis over the sinciput and occiput, the cross diameters —bi-temporal or bi-parietal—which are engaged in the contracted conjugate, may thereby be increased, tend to cause the obstetrician to select version rather than the forceps. Since the invention of Tarnier's forceps, however, the tide of opinion which was setting in favor of version under the conditions named, has been checked, and the forceps are now in greater favor.

Several points bearing upon this question are brought out in a paper by Dr. R. Milne Murray, in the *Edinburgh Med. Journal*, Nov., 1888. He reports two cases of labor in women having flat pelves of minor degree, in which he effected delivery with Tarnier's forceps, as modified by himself. One woman had been delivered once prematurely, and once by turning after the failure of the classic forceps. He delivered her with surprising ease with Tarnier's forceps. The second woman was a primipara, and she also was delivered with comparatively little difficulty. After referring to the general belief that the application of the forceps over the brow and occiput causes an increase in the transverse diameters of the head, he points out that the effect of compression with the axis-traction forceps must be the same as with the classic forceps. To permit of traction a certain amount of compression must be applied, and consequently the locking of the transverse fœtal diameter in the maternal conjugate diameter, if it occurred with the older pattern must likewise occur with the new; and yet delivery is effected generally with the axis-traction forceps with comparative facility in the minor degrees of contraction. This fact throws doubt upon the theory that increase in the transverse diameters does result from the application of the forceps over the brow and occiput.

To settle this point nine recently delivered fœtuses were taken for experiment. A cephalotribe was placed with its blades accurately applied over the occiput and sinciput and the compression-screw then turned until the bones began to show signs of giving way under the compression. At intervals the occipito-frontal, bi-mastoid, bi-temporal and bi-parietal diameters were carefully measured. The occipito-frontal diameter was reduced from an inch to an inch and a half, yet in spite of this very great reduction the transverse diameters underwent hardly any change, although the compression used was far greater than can be made with the forceps. This shortening of the long occipito-frontal diameter without corresponding increase of the transverse diameters, is explained by Dr. Murray by

the fact that the occipital and frontal bones, under the compression of the forceps slide under the borders of the parietal bones—the head "telescopes" from before backward—while at the same time the vertical diameters of the head become elongated. Dr. Murray also considers the effect of applying the forceps obliquely—one blade over one side of the brow, the other over the opposite side of the occiput—and concludes that it is far less advantageous than the application directly over the brow and occiput, since the "telescopic adjustment" is entirely lost, and since the compression of one oblique diameter of the head tends to produce a lengthening of the free oblique diameter.

The experiments of Dr. Murray are of great interest from their bearing on the question of the application of the forceps at the brim of the pelvis. They will go far to do away with the fear of increasing the transverse diameters of the head by applying the forceps over the occiput and sinciput. The experiments are the more interesting as being made in Edinburgh, the home of Simpson, the father and great exponent of the doctrine that, when the head is arrested at the superior strait by contraction of the conjugate diameter of the pelvis, the proper obstetric procedure is version rather than the use of the forceps.

TAMPONNING FOR POST-PARTUM HEMORRHAGE.

There has been considerable discussion of late in Germany in regard to the value of a method of treating *post-partum* hemorrhage which was warmly recommended by Dührssen in the *Centralblatt für Gynäkologie*, No. 35, 1888. This method consists in tamponning the uterus with a long strip of iodoform-gauze, so as to promote contraction of the uterus and to stop the bleeding, partly in a mechanical way, and all with a material which might safely be allowed to remain in the cavity of the womb.

Notwithstanding the successful employment of the method by Dührssen, it has been opposed as dangerous as well as unnecessary, if other well-known methods were used. On the other hand, Dr. Becker, of Hamburg, in the *Berliner klinische Wochenschrift*, Feb. 18, 1889, comes to the support of Dührssen, and by argument and by citing his own experience maintains that the method of the latter is a very valuable procedure, and that it may be relied upon in cases which seem to baffle every other resource of the obstetrician.

In this we believe that Becker is right, and that tamponning the uterus with iodoform-gauze for post-partum hemorrhage is a safe and excellent method. It has never yet—so far as we know—given rise to iodoform poisoning, and it has certainly checked hemorrhages which had resisted other measures faithfully tried before it was employed. There is much in its favor theoretically, and practically it has accomplished about as much as could be asked of any claimant for professional approval.

Of course it will be understood that no such heroic method as this should be employed where a simpler one will do. There are few cases in which intrauterine injections of hot water, and especially hot water with a little vinegar added, will not control post-partum hemorrhage; and, as a clean and convenient method, which leaves no foreign body in the uterus, it is preferable to any other. But, if simple measures fail, one must have more powerful ones, and a careful packing of the uterus with antiseptic gauze might prove of the greatest utility.

—The *New York Medical Journal*, April 13, says that during the four weeks ending Tuesday, April 9, the following numbers of cases and deaths from infectious diseases were reported to the Sanitary Bureau of the Health Department of New York City: Typhoid fever, 32 cases and 10 deaths; scarlet fever, 1,710 cases and 228 deaths; cerebro-spinal meningitis, 12 cases and 8 deaths; measles, 678 cases and 66 deaths; diphtheria, 739 cases and 189 deaths; small-pox, 1 death.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

A TREATISE ON HEADACHE AND NEURALGIA, INCLUDING SPINAL IRRITATION AND A DISQUISITION ON NORMAL AND MORBID SLEEP. By J. Leonard Corning, M.A., M.D., Consultant in Nervous Diseases to St. Francis Hospital, New York, etc. 8vo, pp. viii, 231; illustrated. New York: E. B. Treat & Co Price, $2.75.

The title of the book gives a good general idea of its contents. The first part of the book is taken up with a consideration of headache and neuralgia. In the treatment of the latter he lays great stress upon the value of antipyrin and cocaine. His method of using cocaine is deserving of mention. An instrument is first employed which at one stroke makes a number of needle-point punctures in the skin of the affected area; a sponge electrode saturated with a five per cent. solution of cocaine is placed over the punctures and connected with the positive pole of a three or four cell galvanic battery; another electrode saturated with warm water is placed on the skin near, but not in contact with, the first, and connected with the negative pole of the battery. The current is then passed for ten or twenty minutes, and it causes the absorption of the cocaine solution. To prolong the contact of the anæsthetic with the affected nerve, he has devised the following procedure: a piece of wire gauze, cut to fit the affected area, is firmly pressed into the skin and held there by a suitable compress. This checks the flow of blood in the part and so prevents the anæsthetic from being washed away.

The book is stamped strongly with the individuality of the author. Some exception might be taken to the freedom with which he uses cocaine, for it is by no means free from danger. The book would also be the better for more careful proof-reading. But it is full of useful hints upon treatment, and will well repay the time spent in reading it.

FIELD'S MEDICO-LEGAL GUIDE FOR DOCTORS AND LAWYERS. By George W. Field, LL.B. 6¼ x 4¾ inches, pp. viii, 291. Albany and New York: Banks and Brothers, 1887. Price, sheep, $2.00; cloth, $1.75.

This is an interesting little book, and one which may be useful to many a physician. It is written, we believe, from the standpoint of the State of New York, but it contains valuable information, applicable in all parts of the United States, in regard to the status before the courts of medical witnesses, the decisions in regard to expert testimony, the legal view of insanity, the nature of privileged communications, of abortion, of liability for neglect or malpractice, and the rights of physicians to compensation.

Questions are often asked of the Editors of medical journals which are fully answered in this book, and physicians familiar with its contents would be saved from errors which are sometimes committed through ignorance of the way in which the law looks at subjects which physicians often consider quite differently. Nothing in it is of more interest than the discussion of the physician's liability for malpractice and his claims for compensation; and we would advise any of our readers who are engaged in actions, or suits, involving either of these matters to learn what the book before us teaches, as it may help them very materially.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

243. The Influence which the Discovery of Cocaine has exerted on Ophthalmic Surgery. By Samuel Theobald, M.D., Baltimore, Md. From the *Transactions of the Medical and Chirurgical Faculty of the State of Maryland*, 1888. 3 pages.

244. Is Astigmatism a Factor in the Causation of Glaucoma? By Samuel Theobald, M.D., Baltimore, Md. From the *Amer. Journal of Ophthalmology*, October, 1888. 7 pages.

245. Pulmonary Consumption Considered as a Neurosis. By Thos. J. Mays, M.D., Philadelphia. From the *Therapeutic Gazette*, November 15 and December 15, 1888. 63 pages.

246. Does Special Medical Legislation Improve and Elevate the Practice of Medicine? By G. W. Pickerell, M.D., Indianapolis, Ind. From the *Indiana Eclectic Medical Journal*, October, 1888. 11 pages.

243. Dr. Theobald's paper describes very briefly the advantages of cocaine anæsthesia in operations for cataract, and in the application of agents such as sulphate of copper and nitrate of silver to the eyes, as well as in the treatment of strictures of the nasal duct.

244. Dr. Theobald answers the question which heads his article in the affirmative. In his experience astigmatism—and especially that form of astigmatism in which the meridian of least refraction is vertical, or nearly so—is a very frequent concomitant of glaucoma, and he is disposed to think it has a causal relation with it. His pamphlet contains a brief account of the history of twelve cases which he has studied in a comparatively short time, and which seem to support his opinion.

245. In an editorial in the Reporter, January 26, 1889, we gave an outline of the contents of this pamphlet by Dr. Mays, which indicated the views which it advocates, and our reflections upon them. It will suffice here to say that Dr. Mays states the reasons which have led him to look upon pulmonary phthisis as a neurosis of the pneumogastric nerve—an opinion which is curious enough to attract considerable attention, and which he supports with considerable ingenuity.

246. It is not surprising to find a professed "eclectic" arguing against legislation to regulate the practice of medicine, and any one who reads this pamphlet will not be surprised that its author should undertake the task. He objects to such legislation for various reasons, one of the most amusing of which is: "5. I object, because it places the medical profession under police regulation and servililiaty (*sic*), ignobling the noblest calling of man to that of the criminal code. '*Registration*, smile at it as we may, implies baseness, criminality, the tendency of which is to cast suspicion and dishonor upon him who is required to register.'"

It is painful to observe, also, that he regards the "sickening cant about 'protecting the dear people'" as a mere "subtifuge" (*sic*). This is too bad; and men like Dr. Pickerill can hardly be expected to take kindly to anything which would bear so hard on them.

Notes and Comments.

Medical Examining Boards.

The Alabama *Medical and Surgical Age*, February, 1889, says that the necessity for Medical Examining Boards for different States has been thoroughly discussed by the press of this country during the past year. Those who have taken the position that a diploma from a reputable medical college should entitle the holder to practise medicine anywhere in the United States, and that said parchment is sufficient protection for the people, would profit by seeing the written examinations of a number of graduates who have been examined by the County Boards in Alabama. They can form a meagre idea of some of these examinations by reading in the Transactions of the Medical Association of the State of Alabama the criticisms of the State Board of Censors. These criticisms are as fair and free from prejudice as is possible for any criticism to be; for the State Board of Censors had nothing to do with making the examinations, and in a large majority of instances knew nothing of the applicants. This board reviews the examination papers sent up by the County Boards, and then makes such criticisms upon County Boards and applicants as are thought to be deserving and expedient.

A few of the criticisms made by the State Board of Censors, and published in the Transactions of the Medical Association of the State of Alabama for 1887 and 1888, are then quoted. In making these criticisms, the Board of Censors gives the name of the applicant and the college at which he graduated, but for prudential reasons the *Age* does not give the names.

In reviewing the examination of a graduate of a Tennessee college, the Board says: "Applicant is utterly ignorant of both medicine and English, and the wonder is how any college could graduate, or board license such a man."

The same board says of another Tennessee graduate: "He ought to have been rejected on his spelling, though there was sufficient reason without that. His answers are not only incomplete in every case, but are often incorrect.

Of two Georgia graduates, the board says: 1. "The applicant exhibits a lamentable ignorance of medicine." 2. "He answered almost nothing."

It says of the examination of one of the graduates of a Kentucky college: "Applicant shows the most astonishing ignorance of medicine, and if he carries into practice some of his ideas of treatment, will materially diminish the population of his community."

These are only a few of the many criticisms of a similar nature. They show not only the necessity for a board to examine graduates, but the absolute necessity of a law requiring a preliminary examination to the study of medicine.

Chronic Cocaine Poisoning.

M. Magnan, at the Société de Biologie, lately (*Progrès Médical*, No. 5) described three cases of chronic poisoning with cocaine characterized by marked mental and sensory disturbance. The first case was one in which cocaine had been substituted for morphia in the relief of renal colic. After two months' use of the drug the patient began to suffer from illusions of sight and hearing and neuro-muscular irritability. He discontinued the cocaine for six months, resorting to morphia; but on again resuming cocaine the delusions recurred, the patient feeling imaginary blows on the body, or something under the skin, together with a certain degree of analgesia. At the end of a short time he had an epileptic seizure. In the second case (one of hepatic colic) the same substitution of cocaine for morphia had been effected, and produced very similar effects, also terminating in an attack of epilepsy. The third patient also presented hallucinations of sight and hearing, sensation of foreign bodies beneath the skin, and slight analgesia. M. Magnan pointed out that in its action on sensation and the sensory organs cocaine seemed to resemble the alcohols and absinthe rather than morphia, with this difference, that whereas the influence of cocaine poisoning seemed to operate on the cerebral cortex from the occipital lobes forward, alcohol and absinthe appeared to affect the cortex in the reverse order.—*Lancet*, Feb. 9, 1889.

Insanity and Sex.

The Medico-Legal Society of New York City has sent out circulars containing questions to be submitted to those in charge of insane patients, with a view to finding out what proportion of the insanity in this country is the result of sexual causes. The chairman of the committee in charge of the inquiry is Edward W. Chamberlain, 120 Broadway, New York City, who will be glad to hear from any one having facts on the subject in question to communicate.

Dr. Holmes and His Books.

Dr. Oliver Wendell Holmes, in the course of an address delivered to the Boston Medical Library Association, at the formal presentation of his medical library, said: "The most interesting parts of a miscellaneous medical library are its oldest and its newest portions. Between these is a long, dreary interval, filled up by books not old enough to be curious or even rare, and not new enough to represent the existing state of knowledge. I am thinking especially of works on practical medicine. We care nothing, or next to nothing, for the speculative notions of such writers as Forestus and Fernelius. The theories of Stahl and Van Helmont, of Hoffman and Boerhaave, the conflicts of the Brunonians and the adherents of Cullen, mean as little to the physician of the present as the farrago of remedies with which they puzzled the astonished and indignant viscera of their patients. Still, something may be gained from these obsolete and utterly neglected writers. They were not all fools because they had not the wisdom which comes with the knowledge of a later day. There were, and are always, men of common sense—good, strong, coarse common sense—in the medical profession. Sydenham was one of these. I believe I have hardly ever delivered a medical address in which I have not referred to the 'roast chicken and pint of Canary' which he prescribed for a patient affected with what a Dublin physician might probably call 'male hysteria.' I have always thought it a stroke of genius in Dupuytren—if the idea was original with him, but I have an impression that it was borrowed from an earlier authority—when he ordered a patient to drink the milk of a goat which had been rubbed with mercurial ointment, the patient having a dread of mercury as commonly administered. That was a kind of infinitesimal dosing, and I have no doubt that the patient got as much good from the mineral in the goat's milk as the Sultan did from the drugs in the handle of the bat with which he exercised every day until he was in a free perspiration. But Sydenham's prescription was the best lesson the over-drugging doctors ever got, unless it may be from watchful mothers and keen-witted, observant nurses.

"As I have referred to the infinitesimal dosing business, let me remind you that if you wish to understand the pseudo-scientific vagaries of to-day you will find more instruction in the 'Ortus Medicinæ' of Van Helmont than in any other old work with which I am acquainted. The infinitesimal, or make-believe, dosing is to be found in the chapter entitled 'Butler.' Butler was an Irishman in a Belgian jail, where Van Helmont found him. He had a pebble which he used to dip in oil, then take a teaspoonful of that oil and add it to a small flask of the same oil and apply one drop of this to the ailing part. Then he would give his pebble a lick with his tongue, and clap it in his waistcoat pocket. This whole chapter, 'Butler,' should be read by the student of Hahnemann and by all intelligent students of medical history. The doctrine of the 'mind cure' is abundantly illustrated in other chapters of the 'Ortus Medicinæ,' the date of which in my copy, now yours, is 1652."—*Boston Med. and Surg. Journal*, February 6, 1889.

Clairvoyant "Physicians."

The Legal News quotes the opinion of the Supreme Court of Wisconsin, by Lyon, J., holding that a clairvoyant physician is liable for failure to exercise the ordinary skill and knowledge of a physician in good standing, practising in the vicinity, and not merely to the ordinary skill and knowledge of clairvoyants. If he holds himself out as a medical expert and accepts employment as a healer of diseases, but relies for diagnosis and remedies upon some occult influence exerted upon him, or some mental intuition received by him when in an abnormal condition, he takes the risk of the quality of accuracy of such influence or intuition. There are so many persons now who assume to act as physicians and take the lives of people in their hands that this decision holding them to a strict liability may perhaps be timely.—*Journal of Amer. Med. Association*, April 13, 1889.

Disinfection of Cities and Towns after Yellow Fever.

The *Atlanta Med. and Surg. Journal*, April, 1889, says that the Quarantine Conference which met at Montgomery early in March, refused by a decided vote to endorse the proposition that it is necessary to disinfect a town or city, in which yellow fever had prevailed, but in which there had been no cases for several months, and after the place had been subjected to the frosts and freezings of winter; deeming that the use of disinfectants, under these circumstances, was not only useless but tended to breed unnecessary terror and distrust, not only among the people of the place, but among those of surrounding States.

Brain Softening from Thrombosis.

Renvers (*Deutsche med. Wochenschrift*, Nov. 17, 1888) reports the case of a man 55 years old, who was deaf from bilateral suppurative otitis media from his youth, and who for several years had had a paralytic weakness of the left extremities, as well as left-sided homonymous heminanopsia, with the light reflex intact. This patient developed left-sided hemiplegia and deafness of the left ear after an apoplectic attack. After a few weeks there was a second attack with coma, in which the patient died.

At the autopsy extensive yellow softening was found in the right hemisphere, which had been brought about by arterio-sclerotic thrombosis of different terminal branches of the artery of the fissure of Sylvius. The middle halves of the anterior central convolution and a part of the first and second frontal convolutions were also softened, and a strip of the first parietal gyrus and the whole of the second parietal gyrus, from which the softening extended into the middle gyrus of the temporal lobe and upon the second occipital gyrus. The remaining parts of the brain were intact. In the motor and frontal region the softening was confined to the cortex, while in the other places it stretched to the white matter. In the pyramidal paths there was secondary descending degeneration.—*Centralblatt f. d. med. Wissenschaften*, Feb. 2, 1889.

Case of Colocynth Poisoning.

Dr. Jansen communicates to the *Therapeutische Monatshefte*, No. 1, 1889, a curious case with symptoms of poisoning attributed to colocynth. It seems that a healthy woman, 44 years old, was suddenly taken sick on September 6, after she had brewed as a bug-killer about twenty-five colocynth fruits, which had been purchased at a shop, in a pint of urine. The patient asserts that she poured the fruit whole, without touching it, from the paper in which it came into the vessel, and that in doing so she neither noticed dust nor was conscious of a bitter taste. At noon she complained of severe dizziness, loathing of food, but no vomiting. On the following morning there was violent diarrhœa, which continued two days. At this time there was moderate pain in the abdomen, headache, thirst, loss of appetite, nausea, coated tongue. In the evening she was somewhat chilly. On the third day the throat and face were swollen and painful, but there was no difficulty in swallowing; there were also œdema of the feet which continued fourteen days, and a moderate amount of albumin in the urine. On September 20, the patient was emaciated and complained continually of dizziness on movement, headache, loss of appetite, oppression after eating, belching of wind, weakness and faintness, moderate constipation. Examination showed nothing abnormal in the different organs; the urine contained no albumin; free hydrochloric acid was continuously absent from the stomach for weeks.

How the poison in question could have penetrated into the body seems doubtful. It would be plausible to suppose that it passed into the stomach in the form of a light powder, although the occurrence of a bitter taste in the mouth was denied. It might also have been a volatile poison inhaled in the vapor and so entered the circulation. The hitherto isolated active principles of colocynth—colocynthin, colocynthidin, as well as citrullin—are of course not volatile.

This and similar cases, he says, indicate the need of precaution. The sale of substances such as colocynth, whose highest dose is four and one-half grains, should be governed by more stringent regulations than have heretofore been imposed upon it.—*Wiener med. Presse*, Feb. 3, 1889.

Influence of Eruptive Fevers upon Syphilis.

Marius Auriel, in a recent Paris thesis, expresses the opinion that in the influence of eruptive fevers upon syphilis two different modes of action may be considered. The first is a general influence profoundly modifying the organism and substituting itself for the diathesis so as to cause its disappearance. Except, perhaps, in the case of variola, this curative action is problematic. The second mode of action of dermatoses upon syphilis is purely palliative. "It is limited to causing the disappearance, by a kind of local revulsion, of atonic ulcerations and malignant eruptions which treatment is unable to overcome." Without going as far as Garrigues, who, with Hardy, does not hesitate in a similar case to advise inoculation with small-pox, Auriel admits that this happy local influence exists. Diday has reported one observation in which a rebellious syphilide was seen to retrocede and disappear. The favorable influence of erysipelas in analogous cases has been attested by numerous observations. The truth of the fact is therefore beyond doubt.—*Gazette médicale de Paris*, Jan. 19, 1889.

Case of Eruption from Rhubarb.

At the meeting of the Berlin Medical Society, January 30, 1889, Dr. Litten exhibited an interesting case of drug eruption which had occurred in the patient for the fifth time. On the 23d of January the patient received a prescription for infusion of rhubarb (8 parts to 200) with bicarbonate of soda, and also a solution of chloral to be injected into the rectum. As the patient had before repeatedly had an eruption after taking rhubarb, he at first refused to take it, and indeed received only a teaspoonful instead of a tablespoonful. A half hour afterward, before the chloral had been injected, the exanthem appeared. This consisted of large-sized hemorrhagic maculæ, and of a severe pemphigus, which was accompanied on its appearance with severe chills, and developed especially on the elbows, hands, feet, scrotum and penis. The whole mucous membrane of the mouth, tongue, hard and soft palates was likewise covered with elevations of the epidermis. The separate dark-red spots the size of the palm of the hand remained unchanged under pressure, and had their seat especially upon the trunk, the extremities, the throat and the face. Since the 27th of January the hemorrhagic spots had gradually faded and the pemphigus blisters dried.—*Deutsche med. Wochenschrift,* Feb. 7, 1889.

The Contagiousness of Tuberculosis in Man.

At a recent meeting of the Board of Health of the Health Department of the City of New York a resolution was passed to the effect that Dr. T. M. Prudden, Dr. H. M. Biggs, and Dr. H. P. Loomis, the pathologists of the department, be requested to formulate a brief and comprehensive statement regarding the contagiousness of tuberculosis in man, stating the evidence of the same, and recommending in the briefest possible manner practicable the simplest means of protection from its influence.

Blue-Black Writing Ink.

A correspondent of the *Scientific American* submits the following formula:

Tannic acid	gr. cc
Gallic acid	gr. l
Protosulphate of iron	℥i
Indigo carmine (neutral)	gr. cccxx
Powdered cloves	gr. v
Water	Oi

Dissolve the tannic and gallic acids in the water. To this solution add the iron salt, and filter through cotton. Then add the indigo carmine, and lastly the cloves. One good copy can be obtained from this ink.

NEWS.

—The Governor of Pennsylvania has signed the bill to regulate the practice of veterinary surgery in the State of Pennsylvania.

—The Memphis Hospital Medical College held its commencement March 29, and conferred the degree of Doctor of Medicine on 62 graduates.

—On April 7, the temporary hospital building of the U. S. Marine Hospital Service, at Cape Charles, Va., was destroyed by the surf during a severe storm.

—The Governor of Iowa has issued a proclamation revoking the cattle quarantine against States other than Connecticut, New York, New Jersey, Delaware and Maryland.

—Dr. E. L. Keyes has resigned his position as Professor of Genito-Urinary Diseases, Syphilography and Dermatology in Bellevue Hospital Medical College, and has been succeeded by Dr. Samuel Alexander.

—At the Semi-annual Conversational Meeting of the Pathological Society of Philadelphia, on April 25, Prof. Roswell Park, of Buffalo, will read a paper entitled: A Study of Acute Infectious Processes in Bone.

—The Trustees of the Chicago Medical College at a recent meeting decided to lengthen the college term to seven months, and to recommend an *optional* four years' course. Dr. G. W. Webster has been elected Professor of Physiology.

—A bill prohibiting the sale of tobacco to minors under seventeen years of age, without the written consent of their parents or guardians, has passed to third reading in the Michigan Legislature. It will be followed by an iron-clad bill prohibiting the sale of cigarettes in any form, which bill, it is stated, has many advocates.

—*Daniel's Texas Medical Journal,* March 1889, says that under the laws of Texas the State University has been required heretofore to give medical and law education free. The Twenty-first Legislature, however, has just passed a bill repealing the objectionable clause, and authorizing a charge of $80 per session for instruction in law, and $150 for instruction in medicine.

—The *Journal of the Amer. Med. Association,* March 23, says that an American Hospital is one of the features of the City of Mexico. All English-speaking persons that apply are admitted. Regular contributors

to the Hospital, who subscribe not less than $1 monthly, and Americans without means of support, are entitled to attendance and medical treatment in the general ward, free of all charge. Other persons may enjoy the privileges of the Hospital on equitable terms, and private rooms are provided for such as desire them.

—The Medical and Chirurgical Faculty of Maryland will hold its ninety-first annual session in Baltimore on April 23, 24, 25, and 26. Professor William Osler, of the Johns Hopkins University, will deliver the annual address, on "The License to Practise, with special reference to State Boards."

—The *New York Tribune*, April 4, says: "In the examination of jurors for the trial of Krulisch the fact was developed that a number of the men summoned objected strongly to the hanging of convicted murderers, but could easily reconcile themselves to the thought of executing them by electricity. This is proof in confirmation of the general belief that the new method of execution is more humane than the old. In fact, the substitution of a silent, powerful current of electricity for the gallows, with all its attendant horrors, marks a distinct step forward in our treatment of criminals."

HUMOR.

IT IS WHEN LANDED in the scales of Justice that the weigh of the transgressor is hard.—*Texas Siftings*.

A BOLOGNA BANK CASHIER has absconded. We suppose the detectives will collect evidence against him link by link.

TWO LITTLE MOBILE BOYS were fishing from a wharf the other day, when one of them fell into the water. The other rushed up to a deck-hand, exclaiming: "Save him, mister! He's got de bate!"—*Burlington Free Press*.

NURSE—"We ought to have a piece of soft old linen to bind up Master Rupert's bruise."

Young Mother (anxiously)—"Ought we, Barker?" (To under-nurse) "Jane, go right out and buy three yards of the finest old linen you can get."—*Epoch*.

WHAT WAYS!—"Mamma!"

"Well, my dear?"

"What awfully queer ways these Western folks do have, don't they? I have been reading an article in 'The Stock Breeders' Gazette' that papa brought home, and it says that cows should have their corn fed to them in the ear!"—*Drake's Magazine*.

WASTED EFFORT. — Charitable Visitor (*about to leave the hospital*)—"I never saw such a cold-hearted person as that patient near the window. I read one of Heber Newton's sermons to him fully ten minutes, and he didn't show the least emotion." Attendant—"I'm sure he didn't mean to hurt your feelinks, Mum; he's as deaf as a post."—*Puck*.

OBITUARY.

SAMUEL W. GROSS, M.D.

Dr. Samuel Weissel Gross, Professor of the Principles of Surgery and Clinical Surgery in Jefferson Medical College, died of pneumonia in Philadelphia April 16, in the fifty-third year of his age.

Dr. Gross was a son of the eminent surgeon, Samuel D. Gross, and was born in Cincinnati, Ohio. He received his early education at Shelby College, Kentucky, and subsequently studied medicine in the medical department of the University of Louisville and at the Jefferson Medical College, graduating from the latter institution in 1857. Soon afterward he began delivering lectures on surgical anatomy and operative surgery, and later, on genito-urinary diseases in Jefferson College, and on surgical pathology before the College of Physicians of Philadelphia. For some time he was surgeon to the Howard and the Philadelphia Hospitals, and for a number of years was a member of the surgical staff of the Jefferson Hospital. On April 1, 1882, he was elected one of the Professors of Surgery at the Jefferson College, which position he held until his death.

During the civil war Dr. Gross was a brigade surgeon, with the rank of Major of volunteers, and at its termination he was brevetted Lieutenant Colonel. He was a member of various medical and surgical associations, in whose discussions he always was an active participant, while for a number of years he was a leading contributor to prominent medical journals. He was well known as an author, and was an acknowledged authority on genito-urinary diseases and on tumors of the female breast.

Dr. Gross was a man of warm and generous impulses, a learned and skilful surgeon, and a bold operator. His untimely death removes one of the ablest surgeons of Philadelphia at the height of his usefulness, and will be heard with sorrow by all, especially by those who listened to his instruction at Jefferson College.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

BAKER'S EMULSION WITH HYPOPHOSPHITES OF LIME AND SODA

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO.,
PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

SPECIAL NOTICE.

For the accommodation of Physicians who are unable to leave home for prolonged periods,

The Philadelphia Polyclinic

issues tickets good for three months, entitling the holder to attend one clinic weekly.

The fee for such special tickets is the same as for the ordinary tickets, which are good for daily clinics for six weeks from date of issue. For any one branch, $15.00.

General ticket for all clinical branches, $100.00. For announcement giving full particulars, address

L. W. Steinbach, Secretary,
N. W. Cor. Broad and Lombard Sts.
Philadelphia.

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

Platt's Chlorides is an odorless, colorless, saturated solution of those chloride salts which have proven most reliable and acceptable as deodorants, disinfectants, and antiseptics; is at once clean, powerful and stainless (contains no mercury), and is especially designed for the hygienic uses of the physician and the practical domestic uses of the housekeeper. It destroys the vitality of bacteria or disease-producing germs, while it is not dangerous or disagreeable, the least possible labor is involved in its use, and it is supplied at very slight cost.

It is sold in quart bottles by druggists everywhere, price 50 cents. But as this concentrated liquid admits of dilution, according to the directions on each bottle, with from four to twelve times its bulk of water, each quart bottle really represents about three gallons of disinfectant strong enough for general uses.

From the fact that so many thousands of physicians indorse the preparation and have found it an article of more than ordinary value and usefulness, we believe that in every sick-room, whether the disease be contagious or not, the use of this odorless disinfectant is of every-day utility and sanitary assistance, and does prove an aid and blessing to the patient, and a comfort and protection to the attendants.

To any physician who for any reason may be still unfamiliar with the practical value of Platt's Chlorides a sample will be sent, by express, prepaid, on request.

Address, giving both Post and Express Offices.

HENRY B. PLATT,

36 Platt St., New York.

Clinical Lecture.

SCURVY IN A HEMIPLEGIC. PULMONARY PHTHISIS.[1]

BY FREDERICK P. HENRY, M.D.,

PHILADELPHIA.

ATTENDING PHYSICIAN TO THE PHILADELPHIA AND JEFFERSON COLLEGE HOSPITALS.

Scurvy in a Hemiplegic.

Dr. Henry began his lecture by showing another case of scurvy which, he said, was at least as interesting as either of the two exhibited on the previous Saturday, an account of which was published in the Reporter, April 3.

Dr. Henry then said: the gums are still swollen, spongy, and tender, and at the time of his admission, a few days ago, they were the seat of spontaneous oozing of blood. The anterior surfaces of both tibiæ contain patches and spots of extravasation so numerous as to leave but little healthy skin between them. The arrangement of these patches is remarkable for its symmetry, which is so great that every large ecchymosis and small petechial spot seems to have its counterpart on the opposite side. This symmetrical arrangement of the cutaneous lesions, together with another fact to be presently alluded to, leads me to exclude any participation of the nervous system in the pathogeny of scurvy. Nervous affections, such as neuralgia, and the cutaneous lesions dependent upon them, such as herpes, are generally asymmetrical; whereas dropsy and other symptoms of blood dyscrasia are, as generally, symmetrical.

The mention of dropsy calls to mind certain experiments of Ranvier, which prove that the nervous system may take part in its production. This well known pathologist was unable to produce œdema in the lower extremities of a dog by tying the inferior vena cava. If, however, in addition to tying this vein, he divided the sciatic nerve, œdema made its appearance on the side of the nerve section. The effect of cutting the nerve was to add the dilatation

[1] Delivered at the Philadelphia Hospital, March 29, 1889.

of vaso-motor paralysis to that of passive congestion. While these facts are not wholly, they are undoubtedly in part, applicable to dropsy in the human subject; for œdema resulting from vaso-motor paralysis—acute congestion—is a well-recognized pathological condition. Such a form of dropsy may properly be called neurotic. These remarks are by no means irrelevant. On the contrary, they have a marked application to the case before us, for one patient is hemiplegic on the left side. In such cases, vaso-motor disturbances on the paralyzed side are very common. Whether they are invariable or not cannot be determined, because their presence or absence is not always noted in the reports of cases of hemiplegia. The probability that they are always present seems so great as to amount almost to a certainty.

The paralysis in the case before us has lasted many months and the patient's intelligence is so much impaired that his contribution to the clinical history amounts to little if anything. It cannot be ascertained from him whether the paralyzed leg has been at any time red or swollen. Increase of temperature on the paralyzed side has been often observed in cases of hemiplegia, and Fagge mentions a case in which dropsy, of renal origin, was limited to it. Speculation is needless, in the absence of any positive data concerning the existence of vaso-motor paralysis in this case; but the interesting fact remains that, in a case of hemiplegia, the manifestations of scurvy have been remarkable for their symmetry.

Pulmonary Phthisis.

In this patient, a man 35 years old, there is dulness over the base of the right lung, as may be perceived in any part of the room. In the same region there are bronchial breathing, increased vocal resonance, and sub-crepitant rales, the whole being indicative of a consolidation of the lung which is just beginning to soften. With the aid of the valuable data derived from the clinical history, the diagnosis of pulmonary phthisis is established beyond doubt.

Basal phthisis, as compared with apical, is a comparatively rare affection. According to one authority, the proportion of basal to apical phthisis is as 2 to 1000; according to another as 1 to 70. These figures naturally excite the question why the apex of the lung is such a favorite nidus of the tubercular process, a question which is usually answered by the statement that the proper nutrition of an organ demands that it be functionally active, and that the respiratory movements, which are the chief gauge of the functional activity of the lungs, are least active in the apices. Other reasons for this localization of the tubercular process are derived from a study of the effects of cough. In coughing, the lungs are compressed, and the air containing the irritant exciting the cough is driven into their upper portions. That a certain amount of air in the act of coughing enters the apex of the lung, is plainly proved by observing this act in emphysematous patients whose lungs bulge upward into the supra-clavicular region at each expiratory effort. With this air, as a matter of course, there may be carried into the apex mucus or other foreign substance, and once lodged in this part of the lung its exit may not be easy. Such foreign bodies may excite inflammation which, by lowering the nutrition of the lung, renders it a suitable soil for the tubercle bacillus.

The diminished movement of the upper part of the chest, and phthisis resulting from it, has been attributed to the weight of the arms. This explanation is purely fanciful and is not borne out by clinical experience. James, a recent writer on phthisis, mentions three cases under his observation, in which the arm had been amputated close to the shoulder, and in which phthisis developed years afterward on the side of the amputation.

Cough.—A symptom of phthisis invariably present in greater or less degree, is cough. Theoretically, cough, which is a muscular action intended to expel an offending substance from the air passages, should not be interfered with. Practically, it is found, in most cases, to be altogether out of proportion to the urgency of such requirements. Its frequency and violence depend not only upon the amount of secretion to be removed, but also upon the irritability of the nervous system. This is greater in the young than in the aged and, therefore, in the former, the cough is more distressing. In the insane affected with phthisis, cough is said to be much less prominent as a symptom than in the sane. It is very common for a phthisical patient to have a violent fit of coughing at two or three o'clock in the morning, after which he may sleep until six or seven. This is explained by the fact that during sleep the respiratory centre is blunted and the secretions accumulate until the irritation of their bulk is so great as to rouse it to action. The offending matter having been expelled, the patient again falls asleep, to be awakened by the same cause a few hours later. On rous-

ing a phthisical patient from sleep an attack of coughing will be excited almost invariably. The amount of bronchial irritation which was insufficient to excite cough while he was asleep, immediately does so when he is awakened.

A certain amount of cough is beneficial in phthisis, and should not be interfered with. That which awakens the patient from sleep during the night, and that which occurs at the hour of rising, are of this nature. The offending substances have at such times accumulated in large amount, and must be expelled. If, however, the violence and frequency of the cough are out of proportion to the amount of expectoration—a point which can be decided only by observation and experience—some measures must be adopted for its relief.

Cough is injurious in several ways: 1. By its succussion, it interferes with any possible healing process. 2. It may rupture blood vessels in the walls of cavities or in the trabeculæ traversing them. 3. During the violent inspiratory efforts which attend cough, particles of secretion may be sucked into and infect still healthy portions of lung. Finally, repeated attacks of cough exhaust the patient's strength. They do so both by the fatigue attending such violent muscular exertion and by the attacks of vomiting which often accompany it. This is explained by the close association of the respiratory and gastric centres, an anatomical arrangement which also explains the fact that coughing is often produced by the ingestion of food. It is very common for patients to say that a cough which annoys them is nothing but a "stomach cough." In most cases they are mistaken in their diagnosis, but this does not disprove the fact that cough may be excited in a reflex manner by gastric irritation.

Having decided to relieve the cough, it is better to begin by trying to dispense with that remedy which one is compelled to resort to sooner or later in most cases, viz., opium and its alkaloids. One of the best sedatives for an abnormal irritability of the respiratory centre, is hydrocyanic acid, which may be combined with a tonic as in Begbie's mixture—a favorite English prescription:

℞ Acid. hydrocyan. dil. . . . . f℥i
Acid. nitrici dil. . . . . f℥iii
Glycerini . . . . . f℥i
Infus. quassiæ . . . . q. s. ad f℥vi
M. Sig. A tablespoonful in water, thrice daily, before food.

This, with the aid of the steam atomizer, by means of which a spray of compound tincture of benzoin and water is inhaled, may give great relief. The effect of these remedies may be aided by counter-irritants and cataplasms to the chest. If the cough continues unabated, or if, in the course of time, these measures seem to lose their effect, opium in some form will have to be resorted to. The following mixture, in which the dose of morphia is too large, has long been employed at the Episcopal Hospital:

℞ Potass. cyanidi,
Morphinæ acetat. . . . . āā gr. 1-10
Acet. sanguinariæ . . . . . m̃v
Syr. Tolutan . . . . . f℥ss
Aquæ . . . . . q. s. ad f℥i
M. One drachm every six hours.

It is better to give a smaller dose, say one-twentieth grain of morphia, at shorter intervals. If morphia disagrees, codeine may be substituted for it. Spirit of chloroform is an excellent ingredient of an expectorant mixture. A mixture of equal parts of glycerine and whiskey is sometimes very soothing after the nocturnal attacks of cough, and it may enable the patient to sleep until the accumulation of secretions awakens him in the morning. With such measures as these and with others which will suggest themselves, the cough may be greatly relieved. When dependent upon laryngeal catarrh or ulceration, it will, of course, demand local treatment.

Pain.—Although, probably, no case of phthisis runs its course entirely without pain, the latter cannot be called a prominent symptom of the disease. Pleurisy, as is proved by the firm adhesions with which the two layers of the pleura are always bound together, is a constant accompaniment of phthisis. As a rule, the separate attacks of pleurisy by which these adhesions are effected, are subacute, but occasionally such an attack may give rise to severe pain and marked febrile movement. Such a case is now in the hospital, one in which the pain was so great that pneumothorax was suspected. Great relief may be afforded in such attacks by restraining the movements of the chest with straps of adhesive plaster.

Fever.—An attempt has been made to distinguish two types in the fever of phthisis, an inflammatory and a resorptive; the former depending upon the irritative and inflammatory processes going on in the lung, and the latter upon the absorption of products of inflammation and necrosis. The two types are generally combined in varying propor-

tions, and it is held by some authorities that valuable prognostic and therapeutic data may be derived from a correct estimate of the degree in which one or the other preponderates. The inflammatory is characterized by a high temperature range, with slight fluctuations; the resorptive by marked fluctuations, shiverings, and sweatings. The former is to be treated by absolute rest in bed. Stimulants should be withheld, as a rule, and the drugs should be limited to an expectorant and a saline, such as the liquor ammoniæ acetatis. When the fever is indicative of resorption of inflammatory or caseous products, alcohol should be administered, as it not only tends to steady and lower the temperature but, at the same time, to check the profuse night sweats which so often accompany this type of fever. This brings us to the consideration of this latter symptom—night sweats—which are often so annoying and weakening to the patient.

Night Sweats.—It has been supposed by some that the perspirations are eliminative and, therefore, to some extent beneficial; but there is little ground for such an opinion. They are undoubtedly indicative of nervous exhaustion, and they accompany all sorts of enfeebled conditions in which there is no question whatever as to the elimination of any toxic or infectious material. If in any degree eliminative they are, like the cough, greatly in excess of such requirements. This is proved by the fact that the patient is rendered much more comfortable when they are checked. They may sometimes be controlled by the nocturnal administration of food, such as milk, soup, beef-tea, or an alcoholic stimulant; and such means should be employed before resorting to drugs. Sponging the surface with tepid water containing vinegar, or a little dilute mineral acid, will often prove of benefit. These measures failing, there are two drugs which exert a specific action in controlling night sweats, whether in phthisis or in any other disease, and I say this with great positiveness as the result of a large experience with them. The drugs to which I refer are picrotoxin and agaricin. They are both given in pill, the former in doses of one-eightieth of a grain; the latter in doses of one-tenth of a grain. I am accustomed to prescribe one grain of Dover's powder with each dose of agaricin. One of either of these pills given at bed time will prevent the sweating in many cases, but they may have to be given twice or thrice in twenty-four hours. Atropine, belladonna, and oxide of zinc are doubtless still largely employed in the treatment of night sweats; but in my opinion are much less certain in their action than the two substances mentioned.

Pleuritic Adhesions.—The pleuritic adhesions to which reference has been made as being so constantly present in cases of phthisis, may be regarded to some extent as conservative. The adhesion of the wall of the cavity to the opposite costal pleura will prevent the rupture of that cavity into the pleural sac. Rupture gives rise to what is called pneumothorax. During a paroxysm of coughing, the patient feels a severe pain in the side, has the sensation of "something giving way," and immediately thereafter suffers from the severest form of orthopnœa. The other symptoms are those of collapse in general, such as a cold, clammy skin, and thready pulse. Death may be the almost immediate result of such an accident, or, on the other hand, the patient may survive its immediate effects and succumb to the pleurisy, generally purulent, which is sure to ensue. When death from dyspnœa seems imminent, the pleural cavity should be punctured and the air allowed to escape. The treatment of the ensuing pleurisy or empyema is partly medicinal and partly surgical and does not come within the scope of our subject.

Fistula in ano.—This is a complication of phthisis the frequency of which has been estimated by one authority to be about five per cent.; by others, between ten and fifteen per cent. The responsibility of deciding the question of an operation in such cases should be assumed by the physician, who is better acquainted with the recuperative powers of his patient than a surgeon who is called in consultation can be. If there are decided fever and severe paroxysms of cough, operation should not be undertaken; but if there is little or no febrile movement, slight cough and moderate expectoration, it may be advised, especially if the fistula gives rise to much discomfort and is attended with considerable discharge.

Lung Surgery.—The local treatment of pulmonary cavities is twofold. When seated near the apex, experience has proved that benefit may be derived by injecting into them various antiseptic solutions. The following are recommended: Lugol's solution, iodoform in ether, and solutions of carbolic acid, bichloride of mercury, creasote, and sulphocarbolate of sodium.

It is now a recognized surgical procedure to open certain tubercular cavities, insert drainage tubes, and, in short, treat them as abscesses are treated in other situations.

To be amenable to surgical treatment, a pulmonary cavity must fulfil certain conditions. It should be single, near the surface, and situated in the lower portions of the lung. The thoracic walls in the upper part of the chest are too rigid to permit of that contraction which is necessary to the cicatrization of a cavity. These operations should not be lightly undertaken, for the greatest skill in diagnosis is requisite to the proximate localization of a lung cavity.

There are many other symptoms and complications of phthisis to which want of time has prevented allusion. They are so numerous and varied that a case of chronic pulmonary phthisis may be regarded as an epitome of all other diseases. It is an inflammation, a fever, and an infectious disease; and there is scarcely an organ or tissue of the body which may not be impaired, in structure or function, during the course of the disease. The study of pulmonary phthisis, therefore, although somewhat discouraging from a therapeutic, is instructive in the highest degree from every other point of view.

COMMUNICATIONS.

GONORRHŒAL RHEUMATISM.[1]

BY CASPAR W. SHARPLES, M.D.,
RESIDENT PHYSICIAN, PHILADELPHIA HOSPITAL.

The following paper is based upon the study of eleven cases at the Philadelphia Hospital, chiefly in the wards of Professor Osler.

This subject we find treated of under the following synonyms, viz.: "Arthritie or Arthropathie Blennorrhagique," "Tripper-rheumatismus," "Urethral Rheumatism," and "Urethral Synovitis."

In 1784 the subject was first mentioned by Swediaur under the heading of "Arthrocele, Gonocele, or Blennorrhagic Swelling of the Knee." About the same time Selle recorded a similar note. Swediaur's account is unique, and for its historic interest worthy of repetition. It is as follows:

"A very considerable swelling of the knee (sometimes of both knees and the heel at once), attended by excruciating pains in the joints, sometimes occurs in men after blennorrhagia. These pains, accompanied by more or less symptomatic fever, continue for two or three weeks and gradually go off, leaving a stiffness in the joint, which lasts for many months. The disease particularly affects young men, who, after a debauch, have been infected with blennorrhagia, with which it seems to be intimately connected. It is surprising that no author has treated of this disease, as the consequence or symptom of blennorrhagia. It is not very uncommon, for in the course of my practice I have seen seven or eight cases, each of which came on about the sixth or eighth day of the blennorrhagia, and in every instance the discharge from the urethra was either sensibly diminished or totally suppressed. For want of sufficient observation, I have not been able to determine the character of the disease, but in all cases which have come within my knowledge this disease appeared to partake of the character of gout—with this exception, that all the persons were about the age of twenty-three or thirty, that the color of the skin was not changed, and that the swelling bore handling without exciting pain. The swelling gradually disappears by the free use of mild diluent drinks, and by frictions with the ammoniacal liniment; but above all, with a liniment made of gum ammoniac dissolved in the vinegar of "squills."

In this account we find the key note of many later descriptions of this disease. It is a very good account of that form of the trouble, chiefly affecting the knees, called chronic hydrarthrosis.

There has been, and is yet with certain physicians an idea that no such affection as gonorrhœal rheumatism exists. How we can avoid acknowledging its existence I do not know; for in so many instances it has occurred in connection with gonorrhœa, and in the same cases there has been a return of rheumatism with each subsequent attack of gonorrhœa, without any extraneous rheumatic exciting causes. There is undoubtedly some connection, at least, with urethral conditions. As an example, Basset, of Fournier's clinic, reports a characteristic case, in which there were five attacks of gonorrhœa, and rheumatism with each attack. But a striking feature was that, after every introduction of an urethral instrument, fever immediately followed, and arthritic pains, with conjunctivitis throughout the attack. Rheumatism has existed resulting from irritation due to a stricture.

Petrone has found gonococci in the affected joints. In one case they were found on the fifth day and in another on the third day. Another observer found them the day after the fluid had collected in the

[1] Read before the Philadelphia County Medical Society, March 13, 1889.

joint, but on the fifteenth day they could not be found. Hall reported a case in which they were found to the Clinical Society of New York. These facts demonstrate more than a coincidence between gonorrhœa and rheumatism. Dr. Jameson attempted two cultures from cases, to which I shall refer later; one was a case of hydrarthrosis of the knee, one a case of general articular trouble. Only a negative result was obtained.

In new-born children there is sometimes seen a purulent ophthalmia, which is attributed to gonorrhœal infection during the passage of the head. Rheumatism has in a few instances been associated with this ophthalmia. Lucas reports a case with a good history. A mother obtained gonorrhœa three weeks before her confinement. Soon after delivery, the child had conjunctivitis, with a profuse discharge. Associated with this ophthalmia was swelling of the knee and later involvement of the wrist. Other cases of rheumatism soon after birth have been reported, without mention of gonorrhœal ophthalmia, and probably closer study would show such cases to be similar to Lucas's case.

From the resemblance of puerperal rheumatism to gonorrhœal rheumatism, many cases of the former are probably specific, though there exists a puerperal rheumatism quite distinct from gonorrhœal infection. It is proper to say that after the rheumatism has once appeared it runs a course independent of the urethral state, and does not cease when the gonorrhœa has ceased.

Gonorrhœal rheumatism holds no distinct time relation to the stage of the urethritis. It usually occurs from the third to the sixteenth day of the disease, but is quite common from the third to sixth week, and has been, in connection with gleet, delayed as long as the twelfth month. Dr. Pye Smith has tabulated the time of appearance of rheumatic symptoms in eleven of his twenty-nine cases: In 3 cases during the first week; in 1 case during the third; in 2 cases during the fourth; in 2 cases during the sixth; and in 3 cases during the ninth week.

To this list I would like to add the time of occurrence in nine of my eleven cases. In one case it occurred on the fourth day; in two on the sixth; in one on the twelfth; in one on the fourteenth; in one on the twenty-first; in one about the fiftieth; and in one on the sixty-third day.

Nothing remarkable is to noted as to the time of life at which this disease occurs. In my cases, the attack occurred in three before the age of twenty; in seven between twenty and thirty; and in one above the age of thirty years. The habits of people during the decade between twenty and thirty, and their exposure to infection then, account for the greater frequency of gonorrhœal rheumatism. The parts and the number of parts affected vary much. They do not seem to bear any relation in this respect to the severity or stage of the gonorrhœa. There may simply be an involvement of the synovial membrane, making a true but a specific synovitis. But there are said to be cases of gonorrhœal synovitis which have afterward become cases of arthritis, presenting a joint filled with pus and showing consequent destruction of bones and cartilages. The fibrous tissues around the joints are often first involved with affection, perhaps secondary, of the synoviæ and cartilages. Along with other fibrous tissues we may have involvement of the sclera, and accompanying iritis. The endocardium and pericardium are affected. Ligaments in all parts may be attacked, and it is not rare to have trouble in the fibrous tissues of the spinal column. A point of supposed involvement is the bursa under the os calcis. The sheaths of the tendons are affected, and there is an œdematous infiltration of the skin, which may become hard and brawny. The affection seems to have no predilection for certain joints, for almost every joint in the body has been involved, different parts suffering in different varieties.

In some instances we find a distinct gouty or rheumatic family history, and occasionally a history of a previous attack of ordinary rheumatism. Nolen's record of 88 cases gives six with ancestral rheumatic history, four with previous rheumatism, and twelve with gouty ancestors. Of my cases two had had previously acute rheumatism, and two had a family history in which rheumatism figured.

It affects men oftener than women. Of one hundred and eleven cases there were but seven in women (Nolen). Davies-Colley reports twelve cases of one form of this disease, nine of which were in women. Of the writer's group of cases only one was in a woman. It is stated that prostitutes possess an immunity from this disease, and of this fact I know of no explanation. Five out of nine cases of Davies-Colley's were in pregnant women, suggesting that perhaps a specific trouble in connection with pregnancy may render the person more susceptible to the rheumatic affection. It is usually found in

women who are not prostitutes but who have had illicit intercourse, or in women who have been recently married.

In comparing the relative frequency of gonorrhœal rheumatism in men and in women, there may be an explanation found in the urethral and vaginal constituents. The female urethra consists of muscular, erectile, and mucous coats. The mucous coat has no special glandular communications except the few mucous follicles around the external orifice of the urethra. The male urethra also has the same coats. The mucous coat, however, is a part of the genito-urinary mucous membrane, and is prolonged into the ducts of the glands which open into it—viz., Cowper's, the prostatic, vesiculæ seminales through the ejaculatory duct, and the vasa deferentia. From this greater complexity and sensitiveness, as well as from the greater area of exposed mucous membrane, the attempt is made to explain the frequency of gonorrhœal rheumatism in men. Moreover, the vaginal wall is a tough, thick, and non-absorbent combination of tissues.

The immediate cause of gonorrhœal rheumatism is the specific urethritis. Often it comes without any apparent exciting causes, and at other times there is apparently a dependence on cold, fatigue, injuries, and exposure to wet, such as result in ordinary rheumatism.

Fournier has made three divisions of gonorrhœal rheumatism, which are: (1) Hydrarthrosis of Knee; (2) Polyarticular, as in subacute rheumatism; and (3) Ambulatory pains. But in Pepper's System of Medicine, Dr. Howard makes a division into five classes, viz: (1) Arthralgic; (2) Rheumatic; (3) Acute gonorrhœal arthritis; (4) Chronic hydrarthrosis; and (5) Bursitis and thecitis.

The arthralgic form may co-exist with the more acute forms, as ambulatory pains, shifting from joint to joint, without any swelling or tenderness on pressure, but a decided increase of pain on motion. There is no change in the color of the skin. Such a condition is found in a gonorrhœa of long standing, and without any apparent change in the urethral discharge. The patient is liable to exacerbations of pain. This form does not yield to treatment.

The rheumatic form may come with a premonitory chill, or may follow exertion, strain, exposure, etc.; or it may occur without any of these apparent influences. Rheumatoid pains in the soles of the feet, ankles, loins, etc., lasting a day or so, may precede the trouble. Then there is a sudden involvement of many joints, the attack perhaps coming on during the night. The joints are moderately swollen, are more or less changed in color, and are tender on pressure or on motion. This rheumatic form tends to involve all of the joints, and especially the smaller ones. Regarding the number of joints affected, it is interesting to note that in 120 cases, 212 joints were affected: the knees 83 times, the ankles 32 times, and the fingers and toes 75 times. In 25 cases collected by Pye Smith, the involvement is as follows: the wrist in 6, shoulder in 3, hip in 1, elbow in 1, and the knee in 14. In my 11 cases there were 60 joints affected, distributed as follows: the ankle in 10, wrist in 6, knee in 9, elbow in 4, temporomaxillary in 4, sterno-clavicular in 3, shoulder in 2, hips in 3, and the fingers and toes in seven cases. These eleven cases present twenty-two distinct attacks of gonorrhœal rheumatism. One patient had seven attacks and another three. Nevertheless, with all this general affection there is a tendency for the disease to settle in one joint, in which there may occur an effusion, consisting of leucocytes, flakes of lymph, and serum. Periarticular tissues are more commonly involved than in ordinary rheumatism. This is shown in the marked local œdema and the fusiform enlargements of the fingers. Pain, pseudo-anchylosis with deformity, are quite common, disappearing eventually, though the cartilages and bones may take such a part in the inflammatory process as to cause the affection to resemble rheumatoid arthritis. In this variety we see cardiac, pleural, cerebral, and ocular complications. The urine is often high colored, and contains transiently oxalates, urates and uric acid. Acid sweats are often present as a passing phenomenon. Local sweats are quite persistent. The temperature is not high, though at first it may rise to 103° F., but only to fall soon and remain down, in spite not only of a continuance of the arthritic trouble but also of an involvement of new joints.

Here I would like to submit the report of a few cases, some of which are of more than usual interest from the points they illustrate.

Case I.—H. H., 24 years old, admitted to the Philadelphia Hospital November 19, 1888. The patient's family history was good; there was no history of rheumatism. He is a baker, and is exposed to sudden changes of temperature. Four years ago he had rheumatism in the feet and ankles.

Since then he has had a yearly attack. One attack was of nineteen weeks' duration. All this took place before he had gonorrhœa. On November 3, 1888, he became infected with gonorrhœa, and in eight days there was urethritis with much strangury. On the 17th he had pain in the joints following a wetting on the previous day. The pains were first in the metatarso-phalangeal joints of the great toe of the left foot, then in the great toe of the right foot. The morning before his admission, the fingers of the left hand, and on the 24th the right temporo-maxillary articulation, became involved. A urethral discharge was present on his admission, and continued to be thick and creamy. The joints were swollen and very tender. The pains required morphia to relieve them. The patient was given oil of gaultheria in twenty-five drop doses every two hours, with relief of the pain, and blisters were applied to the affected joints. The temperature was 103° on admission, but fell in two days and ran along about normal for nineteen days. Recovery was rapid, and on December 2, 1888, he was up, the trouble having almost gone from the joint. The urethral discharge had become very thin. On December 4, however, he injured the great toe, which became tender and swollen. On December 12, he complained of being cold, and had a chill followed by a rise in temperature to 101$\frac{4}{5}$°. The first phalangeal articulation of the left hand and the left knee became swollen, and there was at the same time pain in the back. The urethral discharge was also increased. On the 27th the patient was discharged, with some stiffness of the joints and some enlargement of the fingers. An examination of the heart, early in the attack, showed that the apex beat was in the fifth interspace, inside the nipple line; there was no thrill. There was a distinct blowing systolic murmur at the apex and at the aortic cartilage. In May, 1888, the patient was in the hospital with rheumatism, and in a note made on his dismissal I find this statement: "Heart was carefully examined and no lesion found." His urine was acid and contained only pus cells.

Case II.—O. C., 31 years old, a paperhanger, was admitted to the Philadelphia Hospital November 4, 1888. There was no family rheumatic history. The patient has been a heavy drinker. When twelve years old he had inflammatory rheumatism. In 1876 he had his first attack of gonorrhœa, from which he recovered in three weeks. In July, 1884, he again had gonorrhœa, and in a few days gonorrhœal ophthalmia. The urethral discharge ceased in a few days, following four injections. His urine stopped for a few days. Soon he had soreness in the great toe of the left foot. The left ankle and knee, the right shoulder and right hip, the ball of the great toe, and left shoulder became affected in the order named. For this attack he was in bed six months, being unable to move or feed himself. For a year he was compelled to use crutches. During this attack the urethral discharge did not reappear. Preceding the joint trouble he had a thorough wetting, and convalescence was slow and gradual.

In September, 1886, he had a third attack of gonorrhœa, the discharge appearing four days after infection. During the progress of the gonorrhœa his ankle became swollen (the result of an injury as he thought), disabling him from September to January. At that time he was in bed five weeks. His present attack dates from October 13, 1888, when he became re-infected. Urethritis appeared in a few days and lasted a day or so after using injections. The urine was scanty and passed frequently. On the eighth day he first had pain in the back and about the heart; he had never before experienced pain about the heart. The right hand and left foot were next affected, as was also the right wrist. The wrist and ankle were swollen, red, and tender; it was impossible to move them. The patient said he had had a great deal of fever before his admission. Shortly after admission the left knee was affected; then the right great toe and left foot, and then the sterno-clavicular articulation. The temporo-maxillary articulations on each side were much swollen and tender, so that he could not open his mouth. On October 26, his eyes became sore, with some discharge. There were intervals of days when the pains would be less, only to be followed by a recurrence, with painful and tender joints, for five or six days. The trouble was chiefly situated in the right knee and wrist. On December 21, 1888, he was discharged, with the right knee still somewhat swollen and stiff. The right hand could not be closed. On the patient's admission there was a distinct systolic murmur at the apex, which persisted during his stay, though its intensity became much less. The urine was strongly acid. His temperature, on admission, was 97°, but soon rose to 101$\frac{1}{5}$°, ranging between that and normal, rising sometimes, as a new joint was affected, and often with no apparent cause.

Treatment was with oil of gaultheria,

which seemed to lessen the pains and control the temperature; arseniate of iron was also used, but had no effect. The patient was given hot whiskey and pilocarpine, to produce sweats, and after the sweats he felt much better. Apart from these no sweats were noted in the course of the disease.

Case III.—W. L. C., 28 years old, was admitted to the Philadelphia Hospital December 12, 1888. There was no history of rheumatism in his family. The patient is a moderate drinker. Four years ago he had gonorrhœa, which followed three days after infection. In four days he had pain in his left foot, which continued for sometime before any swelling appeared. The left foot, the right knee, both hands, the fingers, elbows and temporo-maxillary joints were affected. With this attack he was in bed three months; he did not have much fever, but had heavy night sweats. After getting up, the left ankle remained sore and stiff for a long time.

The present attack began four days after the urethritis, and not after any unusual exposure. The secretion did not lessen when the joint trouble began. Pain appeared in the foot before the joints were involved, and affected the left toe, left ankle, right great toe and elbow, in the order named, with slight swelling. The elbows were extremely painful on exertion. On Dec. 27, 1888, he had an exacerbation of the pain in the elbow and right foot. He had conjunctivitis during the first attack and also in the exacerbation. The man had on admission a well-marked aortic regurgitation, which seemed to suffer no change during his stay. He had oil of gaultheria, local urethral treatment, and calcium sulphide in doses of ¼ to ½ grain, three times a day. He left the house with moderately good use of his joints, though they were stiffened. The Resident in charge of the case says that he thinks the calcium sulphide had some effect.

Case IV.—J. C., 28 years old, was admitted on October 9, 1888. The patient says that his father had rheumatism. He is a laborer and is much exposed to wet and cold, and has had gonorrhœa four or five times before the present attack, with the last of which, four years ago, he had a bubo. On July 28, 1888, he again had gonorrhœa, acutely for several days. On August 2, 1888, as a result of treatment, as he thought, the discharge ceased. Four days afterward he felt the first pain in the joint; the pain had been preceded for several days by constitutional disturbance and fever. On August 6, 1888, the pain appeared in the right ankle and on the 8th in the right knee, but without any swelling. He then entered the hospital. The left ankle and knee, right hand, and left wrist were involved in the order mentioned. Then followed the involvement of the right elbow and shoulder, and of the sterno-clavicular articulation. The temporo-maxillary joints and hips were also slightly affected. The most intense inflammation was in the left wrist and in the sheaths of the tendons along the dorsum of the hand. The affection here has been most acute and the swelling extreme, of a dense brawny character. The skin was dark and very firm in this region. On November 15 a fly-blister remained on for twenty-four hours without effect, as it did also on the 21st. Off and on, there was an orchitis of the left testis, and accompanying it a renewal of the urethral discharge, as a thin pus. In one attack, commencing Nov. 23, the testis swelled rapidly, with great pain extending up into the abdomen. The scrotum was much thickened. The urethral discharge persisted with the orchitis, and the two seemed to subside together gradually. About Dec. 11, there was a fresh outbreak of articular mischief, which appeared in the first phalangeal articulation of the right middle finger, and extended to the metacarpo-phalangeal joints. The thumb of this hand was also affected. The temperature rose to 103°. Dec. 16, there was well-marked lymphangitis of the right arm, red lines, $\frac{1}{16}$ of an inch in width, extending from the seat of inflammation, with enlarged axillary glands and a temperature of 101° on the evening of the 17th, subsiding on the 18th. Dec. 20, there was again much swelling and pain in the left testis, with return of the urethral discharge, which had been absent for the preceding six weeks. Dec. 27, the right shoulder became very sore, and next day there was swelling of the right sterno-clavicular articulation, which was very red. Jan. 5, the left testis was again swollen, with return of the urethral discharge, burning micturition, and chordee. The testicle was not so large as upon former occasions. At each attack the swelling and urethral discharge were less, but this was the first occurrence of chordee. A few days before this attack of orchitis, there was pain in the shoulder. The right sterno-clavicular joint again became swollen and looked as if suppuration was going on, but no pus was found on opening it. Jan. 10, the patient was quite comfortable. The left wrist was stiff, the parts atrophied, the pain nearly gone, the legs and the sterno-clavicular

articulation swollen. Since the last attack he has been in about the same condition.

The temperature in this case has presented the following features. On admission it registered 100°; the second evening 101⅖°, the next morning normal, and then it gradually rose until the 12th, when it was 100⅖°; on the 15th, when there was much pain, it was 101⅖°. From this time until the 28th it ranged from 99°–100°. Dec. 4, it rose to 102°, and since then it oscillated from normal to 101°. The highest record was 103°, which occurred during the trouble with the right hand. Quite early he had some sweats, which ceased; later he had night sweats and local sweats of his legs. After about six weeks some change was noted in the first sound of the heart, and subsequently a murmur became quite plain. In the treatment, means have been quite exhausted and without any result. Poultices and lead water and laudanum were used to no avail. The hand was put on a splint and bichloride towels were applied with marked relief. Oil of gaultheria had no effect. The patient was put on bichloride, iodide of potash, and arseniate of iron without effect. Morphia was administered to control pain. The parts were wrapped in cotton wool.

The above cases very well show, I think, that endocarditis does occur in connection with gonorrhœal rheumatism. In Case I there is a distinct note of absence of heart lesion, and of its subsequent appearance without any intermediate cause except gonorrhœal rheumatism; though it is possible that this may be a coincidence of gonorrhœa and rheumatism, and that the gonorrhœa acted as an exciting cause. In Case II there were noted the changes and symptoms of acute endocarditis and the gradually diminishing murmur. In Case III, though there is no positive evidence that the heart lesion was due to gonorrhœa, yet there is the history of a previous attack of gonorrhœal rheumatism and the absence of other rheumatic affections; and we know the proneness of the disease to affect the aortic leaflets. Case IV developed under observation as reported. Cases of gonorrhœa have been reported in which endocarditis occurred, without any rheumatic complications, though the endocarditis in these instances may have only been coincidences. One case, ulcerative endocarditis came on in the course of gonorrhœal rheumatism. Certainly endocarditis may appear in this disease, though proportionately much less frequently than in ordinary rheumatism.

(*To be concluded.*)

ARTHRECTOMY OF THE KNEE-JOINT AS A SUBSTITUTE FOR EXCISION.[1]

BY JOHN ASHHURST, Jr., M.D.,
PHILADELPHIA.
PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF PENNSYLVANIA.

The case brought before you to-night is of some interest, being illustrative of an operation which is attracting a good deal of attention among surgeons, especially those who have to do with diseases of childhood. This is a comparatively new operation, having been first suggested by Wright, of Manchester, some seven years ago. His first case was recorded in 1881. He has operated in a certain number of cases since then, but it has been within a very short time, hardly over a year, that the procedure has been taken up by other surgeons. It is now practised by Owen and Parker, of London, and by others. It has been adopted in Germany and in France. In France the sentiment is rather against the operation. The opinion of the majority of French surgeons who have employed this substitute for excision is, that it is equally as dangerous, and the result no better, and in some respects not as perfect. In Germany the sentiment is more favorable to arthrectomy, and in England it is still more so.

My experience with this operation is very limited, as I have employed it only twice. The second patient is still under treatment, and the case which I record to-night is, therefore, the only completed one which I have to report. I think that, as far as a single case can, it shows that the operation is a good one, and that it has a distinct field of usefulness in cases in which the surgeon hardly feels justified in resorting to excision. The history of this case is as follows:

The boy is twelve years of age, with a good family history. The father is living and healthy, the mother living and phthisical; but whether or not there is a tuberculous taint inherited from the mother is uncertain. The belief of the family is that the mother's health was broken down by nursing this boy, and that the phthisis was developed after his birth. The lad was under my care, in the Children's Hospital, more than seven years ago, when five years of age, for the same condition of the knee-joint. At that time I divided the hamstring ten-

[1] A verbal communication made at the meeting of the College of Physicians of Philadelphia, February 6, 1889.

dons and applied a splint, and he left the hospital. This is a practice that I have followed for a number of years in young children, for excision is not a very successful operation in the earliest years of life. In this way a serious operation can often be postponed for some time. The patient returned to the hospital this fall, having in the meantime been under the care of the surgeons in the out-department. His knee-joint, while not getting much worse, did not get better. It was one of those cases which seem too bad to be let alone, with no prospect of benefit from conservative measures, and, on the other hand, not bad enough to justify any very dangerous operation. This seemed to be a case in which it might be proper to do this comparatively new operation of arthrectomy.

The term arthrectomy might properly be applied to the operation of excision itself, but it is understood as applying to the removal of all of the diseased soft tissues, without disturbance of the bones. Some surgeons have employed a longitudinal incision on one or both sides, passing behind the patella and scraping away the soft tissues. Others make the incision across the patella, saw through that bone, clear out the joint, and bring the two segments of the patella together with stitches. The plan which I have adopted, and which is, I think, preferable, is to make the incision just as for excision, below the patella, through the ligament, turning up the patella and getting full exposure of the joint. Then with knife, scissors, and curette, I carefully remove all morbid tissues that can be dissected out, the synovial sac, semilunar cartilages, and any portions of the articular cartilages and bones that may be diseased. The greater portion of the synovial membrane can be dissected out with the knife, scissors, and forceps. The portion at the back of the joint cannot well be thus dealt with, but can be removed with the curette. The articular cartilages should be thoroughly scraped. If any patches of carious bone are found they should be removed. A drainage tube is then inserted, the wound closed, and the limb placed on a posterior splint just as after excision.

This boy was operated on October 3, 1888. Here is his temperature record, which was kept for two months. It shows that there was very little reaction from the operation. The highest point reached was 100.6°, and that upon only one occasion. On five occasions it reached 100°. The result of the operation is an almost perfectly straight leg, with firm union between the articular cartilages. Some surgeons have attempted to obtain motion, but I think it better to be satisfied with fibrous anchylosis. This is simply imitating Nature's mode of effecting a cure in comparatively mild cases, where fibrous anchylosis takes place. In the same way, excision is an imitation of Nature's method of effecting a cure in bad cases, that is, by bony union.

The advantages of this operation over excision are, in the first place, that the length of the limb is not interfered with, and that there is no risk of consecutive shortening. One of the most serious prospective risks after excision is, that from implication of the epiphyseal cartilage, the growth of the limb may be prevented. Most surgeons are familiar with the case of Mr. Pemberton, of Birmingham, where the shortening amounted to eight or ten inches. This is, of course, unusual, but there is risk that the limb will not grow in proportion to the rest of the body. As this operation does not involve the epiphyseal cartilage, there is no risk of consecutive shortening. In the second place, the shape of the limb is preserved. This is, however, a point of minor importance. In the third place, there is no risk of that inward turning of the lower portion of the limb, so common after excision. Surgeons who have done many excisions are familiar with the fact that it is sometimes almost impossible to prevent a certain amount of axial deformity, the lower part of the limb turning in while the upper part rolls out. In arthrectomy the condyles are preserved and the head of the tibia fitting between them prevents the occurrence of this deformity.

An objection to the operation urged by French writers is, that there is apt to be consecutive flexion. This also occurs after excision, and can be avoided by maintaining a firm support as long as may be necessary. I think that in a case like the present it would be better to perform arthrectomy and then retain a plaster bandage or a leather support for even a long time, than it would be to perform excision.

I, of course, do not suppose that this operation will ever take the place of excision, for the majority of cases in which operative procedures are called for are so far advanced that excision is the only remedy; but there are cases in which the disease is limited to the soft parts, and here this operation has its legitimate field. In this case the boy had been under observation for eight years and the condition had finally become so bad that

it seemed necessary that something should be done. There are then a certain number of cases in which this operation may properly be performed, coming in between the simple rectification of the deformity by tenotomy and the graver operation of excision.

It is about four months since this limb was operated on. It is now strong, and the boy can walk on level ground without crutches. He does not require a high shoe. Before the patient goes home, a plaster bandage will be applied, and he will wear this for a long while, reporting from time to time, so that the occurrence of consecutive flexion may be avoided.

CONTAGIOUSNESS OF ERYSIPELAS.

BY CHARLES P. WOODRING, M.D.,
MEADVILLE, PA.

I was called on March 13, to see Emma W., who was suffering with a sore throat. Upon inspection I observed the usual appearance seen in diphtheria, including a decidedly characteristic membrane. Belle W., 13 years old, and two years younger than her sister Emma, was also suffering from the same disease; but hers was evidently a much milder attack and manifested itself three days earlier. When Emma's diphtheritic symptoms, both local and general, were at their height, she developed facial erysipelas, upon the appearance of which the patient referred *all* her pain and distress to the dusky-red, hard and swollen cheeks, to which the erysipelas was limited.

With the increase of the severity of the skin affection came a corresponding decrease in the severity of the local diphtheritic symptoms. This inverse ratio continued until the entire disappearance of any and all throat symptoms.

While the erysipelas was in full bloom, and just after Mrs. W. had applied one of the frequent dressings to it, Edward E., who was visiting the afflicted family, came into the room and asked Mrs. W. to dress a little cut upon the middle finger of the left hand, which he had a minute before inflicted upon himself. Mrs. W. immediately complied with his request, and nothing more was thought of the finger until twenty-four hours later, when Edward began to suffer the most excruciating pains in the injured finger. The pains, however, were not confined to the finger, but extended thence to the wrist, forearm, arm and axillary space. My attention was then, for the first time, directed to this additional patient, whose finger then was only slightly swollen. The course of the lymphatics could, nevertheless, be distinctly traced all the way to the axilla. In a few days all of the worst symptoms of phlegmonous erysipelas had developed in the finger, which soon became the seat of extensive sloughing, and evident necrosis of the phalanges, while the swelling extended in alarming proportions and with the greatest rapidity to the elbow.

The treatment in all of the cases mentioned was supporting throughout: tincture of the chloride of iron, sulphate of quinine, whiskey, milk, and beef-tea internally, and for the diphtheria, turpentine locally. For the facial erysipelas a solution of sulphate of iron was used locally, and for the phlegmonous erysipelas of the finger hot water dressings were first used, and afterward deep and numerous incisions with charcoal poultices, followed by solutions of carbolic acid.

It is generally admitted that all forms of erysipelas must be preceded by a solution of continuity for the ready admittance of a blood poison. Possibly the facial erysipelas in the foregoing case owed its existence to the preceding diphtheria, but undoubtedly the digital erysipelas could claim the facial erysipelas for its parent. The case of phlegmonous erysipelas proves at least, if it proves nothing more, that we cannot be too careful in the handling of patients with facial erysipelas, both for our own safety and for that of other members of the household with whom we come in contact.

A SEDATIVE AND LAXATIVE MIXTURE FOR FUNCTIONAL NERVOUS DISORDERS.

BY J. B. JOHNSON, M.D.,
WASHINGTON CITY, D. C.

A young physician who is called to treat the various nervous affections of women, sometimes finds himself in doubt in selecting a suitable prescription, which will, in the larger number of such cases, meet the indications calling for prompt, pleasant and efficient relief. These disorders are known by the familiar name of functional nervous diseases, and all of them, to a greater or less extent, are attended with vitiated secretions of the alimentary canal, and constipation; and these conditions always aggravate nervous disorders.

The usual causes of these functional nervous diseases are: chronic ovaritis, subinvolution of the womb, and painful menstruation. These derangements of the female organs of generation are foretold by mental depression, mental worry, nervous headache, sick stomach, sleeplessness, and those forms of menorrhagia that are often symptomatic of ovarian irritation or subinvolution of the uterus.

To allay the distress caused by these functional disorders, it is very important to have absolute rest in the recumbent posture, in order to give the organs involved time to regain and resume a healthy discharge of their functions. The next duty is to correct the vitiated secretions of the alimentary canal and to relieve constipation. For this purpose I know no better mixture than the following:

℞ Magnesiæ Sulph., ... ℥ j
Aquæ Camphoræ, ... f ℥ v
Olei Menth. pip., . . . gtt. ij
Glycerini, ... f ℥ j
Potassii Brom'di, ... ℥ ss
Tinct. Hyoscyam', ... f ℥ iij

M. Sig. Shake well. Dose a tablespoonful every three hours

Should the tongue be much coated it will be necessary to give an alterative dose or two of calomel; and should it become advisable, a vegetable tonic may be added to the mixture with advantage. For this purpose the compound tincture of gentian, in half-drachm doses, will act well; and should menorrhagia or leucorrhœa be present, twenty drops of the fluid extract of ergot can also be added with beneficial results.

—Dr. Robert Abbey, of New York City, will address the Philadelphia County Medical Society, May 1, on Lateral Anastomosis of the Intestine.

—A Press dispatch from Mobile, Ala., to the daily papers states that all the condemned articles at the old Quarantine Station on Ship Island, opposite Biloxi, were destroyed by order April 12, and the Yellow Fever Hospital and fixtures and every particle of matter supposed to be capable of carrying infection were burned. There was a great mass of bedding, clothing, and refuse left there when quarantine was moved in March to Chandeleur Island, and as the mass was known to be infected with germs and visitors were not prevented from going on the island, there was a call through the press for its burning, with the result just mentioned.

Society Reports.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Stated Meeting, February 6, 1889.

The President, D. Hayes Agnew, M.D., in the Chair.

Dr. Wharton Sinkler communicated the following on

A Case of Pott's Disease from Injury, Followed by Complete Paraplegia. Treated Successfully by Suspension.

History of Patient.—John T., eighteen years old, native of Ohio, was admitted to the Orthopædic Hospital and Infirmary for Nervous Diseases, February 16, 1888. Father and mother both living and healthy. He is the eldest of three children; others are healthy; there is no history of consumption in the family; has never had any of the diseases of childhood; always healthy and strong.

In September, 1886, some of his schoolfellows "bumped" him against a tree. This was done by four boys, each taking a leg or arm and bringing the buttocks forcibly against the tree. Acute pain in the spine was produced by this at the time, and afterward, in either sitting or standing, pain was remarked; but when lying on his back he was comparatively easy and free from pain. The pain was first greatest in the epigastrium and radiated thence into the back, down into the legs, and up into the shoulders. About three weeks after the injury, he accidentally discovered a lump in the dorsal region of the spine. Soon after observing this, the lump became very painful and was sensitive to the touch. He continued to sit up and walk, but progressively became weaker, and after the second week in January, 1887, was unable to walk at all.

About three months after the injury, he began to lose sensation in the legs; the knees began to get stiff in the spring of 1887. He has been unable to sit up, but was comparatively comfortable in bed.

Condition on Admission.—A tall, slim boy; weight eighty-four pounds; angular curvature at seventh dorsal vertebra; can sit up with the aid of a leather corset which he has worn for some months. He is unable to move the legs at all; knees and ankles generally in a state of rigidity; knee-jerk grossly exaggerated; patella clonus present;

ankle clonus very marked on both sides; toe reflex present—(this is very striking on both sides). The condition known as *spinal epilepsy* readily induced; plantar reflex exaggerated; no cremasteric or abdominal reflex can be elicited; sensation is impaired, but is not lost. He can localize and distinguish touch anywhere on legs or feet; no interference with the functions of bladder or rectum. There is no pain in the spine.

There is a bed-sore the size of a ten-cent piece over the sacrum. The circulation in the legs is poor; the feet are constantly cold. His temperature is above normal, morning and evening; varying from 100° to 102° F. in the evening; in the morning, 99° to 100° F.

He was ordered massage, and the cautery was used on each side of the angular curvature. He was also ordered cod-liver oil and milk-punch. A plaster jacket was applied soon after his admission, but as he fainted before the plaster could set, it had to be removed, and in two days a second jacket was applied. This could be borne only for three or four days, on account of interference with respiration; and it was removed on the second day. A third jacket was applied at the end of another week, and in this he was comfortable. The bed-sore, however, continued to increase in size and depth.

On March 18, he was suspended by means of a padded leather chin and occipital piece from a bar of iron projecting over the head of his bed. This was placed high enough above the bed to allow him to sit upright upon the bed. He was able to bear the extension for nearly five minutes on the first day. On each subsequent day the time was extended, until he was able to bear the extension for half an hour twice a day.

On April 17, the plaster jacket having been removed on March 29, ice and hot water were applied to the spine over the region of the curvature, for ten minutes four times each day—the ice and hot water being applied alternately; first the cold, followed by the heat.

May 14, he was placed in a chair, and extension made from a rod attached to the back of the chair and bent over the head.

About this time he began to have slight power of motion of the toes; this was followed by power to flex the feet, and to flex the thighs.

June 25, fluid extract of ergot, twenty drops three times a day, was added to the treatment; and this was continued until July 31.

July 23, the following note was made: Condition much improved; complains of no pain; can move the legs, drawing up the knees lying on his back in bed; sensation is improved, but is not perfect; clonus is less, but still marked; knee-jerk still exaggerated; toe reflex still present.

The application of heat and cold to the spine was continued until October 18.

In August he was able to lift the feet from the floor as he sat on the chair. One of Kolbe's spinal apparatuses was applied on July 31, and he has continued to wear this when sitting up ever since; it is removed when he is in bed. In the middle of August he could walk a few steps in the wheel crutch.

In October he began to walk about with crutches. He has continued progressively gaining strength in the legs, and is now able to walk about at pleasure, but has not yet been allowed to dispense with his crutches, although quite strong enough to do so.

His weight is now ninety-seven pounds. There is no tenderness over the curvature, but there is no material change in its shape. The reflexes are all still exaggerated, but to a moderate extent; and the tremor of the legs is no longer excited by moving them vigorously.

Reports of Clinics.

UNIVERSITY HOSPITAL.

GYNECOLOGICAL CLINIC.—PROF. GOODELL.

Removal of an Ovarian Tumor.

While the gentlemen are assembling I shall make some remarks on the case before you. This girl is only sixteen years of age. Her health was good until one year ago, according to her statement; but her physician thinks that it was two years ago that she received the following accident. She and another girl were walking when she suddenly fell on her back, and her companion fell on her abdomen. The patient was menstruating at the time. The next day the pain ceased, but she "began to swell" and has never had but one menstruation since that time. She has lost much flesh, and is now merely skin and bones.

We ask ourselves the question: What is this tumor? It is clearly a cyst. Upon making an examination *per vaginam* I find that the uterus is small, and not connected with the tumor. Hence I am disposed to say that it is an ovarian growth. But if it

is true that it has come in only one year, it is probably malignant.

In these large tumors I prefer the use of chloroform to ether for anæsthesia, because it does not tend like ether to congest the kidneys and suppress the secretion of urine. From this cause I have lost patients after laparotomy. My last thirty-four cases of oöphorectomy have been done mostly under chloroform, and they have all been successful. Then again chloroform does not tend to cause œdema of the lungs, which in the aged is liable to result from ether narcosis. In large tumors, such as this one is, the diaphragm cannot play while the patient lies on her back, and we are often compelled to give the anæsthetic and to empty the cyst while the patient lies on her side.

Now after thoroughly cleansing the abdominal walls with a 1 : 1000 bichloride of mercury solution, I begin my incision about four inches above the pubes, making it first down to the preperitoneal fat and then down to the tumor. I examine carefully for adhesions, and I find that I have mistaken the adherent peritoneum for the wall of the tumor. Fortunately I discovered my mistake before doing any mischief; but let this serve to impress upon you how very careful we have to be. Before going further now, all bleeding has to be stopped. In opening cysts the rule is to tap them high up, because the trochar will travel down as the fluid is removed, and otherwise the collapsed cyst may slip off from it. The fluid now ceases to flow, not because the whole cyst has been emptied, but because the cyst is multilocular and only one compartment has been emptied. There is another cyst and a solid body, which we must cut into. I leave these for a moment, while I examine higher up. I find that there are adhesions everywhere, though they are not very strong. I now extend the incision higher up in the median line, nearly to the navel. The catch forceps are more difficult than usual to apply, on account of the œdematous condition of the skin and underlying fascia. I now break up adhesions and incise the other cyst. It is smaller than the first one; but the fluid is thick, dark colored and probably irritating, so that I use every precaution to prevent its getting into the abdominal cavity, which I now enter after washing my hands. I have nearly detached the cyst from the front of the abdominal parietes. The omentum is also attached to the surface. To expedite matters, I catch it up in a pair of forceps and cut it away from the cyst. Within the cyst is a solid tumor, which I cannot reduce in size; and as the pedicle is quite broad and short I shall clamp it and cut off the tumor, so as to get more room.

Cleaning first the outside of the abdomen and packing the inside with sponges, I avoid the introduction of any septic matter, which might set up septicæmia. On the broad slender pedicle I introduce a sort of cobbler's stitch. That is to say, I transfix the pedicle three times before tying the ligature. As the pedicle is so short and broad I shall be on the safe side and put on another ligature, to prevent any possible hemorrhage. I now cut away the redundant portion of the pedicle-button, lest it might slough.

We now tie the omentum, which is held by the forceps *en masse*, and drop it. The removal of the omentum is a small affair. It is not a vital organ, and when necessary I have removed pieces as large as my hand. As such a procedure is not necessary now, I simply drop it back into the cavity.

As our patient is young, I wish to save the other ovary if it exhibits no symptoms of disease. It looks healthy, and as she has menstruated from it at least once since her illness began, I shall leave it.

I now put in one sponge in front of the bladder, another behind the womb, and a large flat sponge on both flanks, and one in the middle, over the intestines. Now, having protected the abdominal cavity, I search for any vessels that need ligating, first on the wall. There is very little bleeding anywhere here; but, if there were, the sponges would show it. Let me count the instruments while the sponges are in.

I now pass the sutures from within outward, because it is easier and safer. I include the peritoneum and the rectus muscle. The tumor does look like a malignant one, yet in apparently innocent cases I have seen growths develop on the pedicle and metastatic cancers riddle the liver. This is a case for drainage, because such a large raw surface as the pedicle and the denuded abdominal walls present will secrete a fluid very favorable for the development of septic germs. I put in four stitches to the inch, because there is less danger of hernia than with a smaller number, and I take in a good deal of all the tissues in every stitch. The largest tumor I ever removed weighed one hundred and twelve pounds. The patient recovered, but with a troublesome redundancy of abdominal skin. I have removed several weighing over eighty pounds, one of which was removed last Thanksgiving day. But the longest incision I ever made was in

a successful case of hysterectomy, in which a fibroid weighing forty-four pounds was removed.

The operation to-day was not difficult, because the adhesions were easily broken down. Dr. Adler has weighed the tumor, and now tells me it tipped the beam at fifty-five pounds; but we must have lost several pounds of fluid on the floor, so that it comes very near the sixty pounds that I predicted it would weigh. We now flush out the cavity of the abdomen with several pitchers of water, although I do not think anything got in it from the tumor. I did not empty the bladder before the operation, because the presence of the urine serves to show where the bladder is, and saves it from injury.

I now paddle about and wash the intestines in the water. Such a procedure we would not have dared to do some years ago; but we now know that it is not the exposure and handling of the intestines that do mischief, but septic filth.

After this laundry of the peritoneal cavity, the sponges are removed and a drainage tube put in. I bring out the stitches close to the margin of the wound, so as to prevent doubling in of its edges. The wound being closed it is dressed antiseptically, with iodoform and iodoform gauze. The bowels will be opened on the fourth day, because otherwise the large pedicle may get fastened to an intestine and cause fatal obstruction.

The drainage tube will be pumped out every two hours for the first day, less frequently on the second day, and it will be removed as soon as the fluid withdrawn from it is straw-colored.

The patient will have no nourishment for twenty-four hours, and will have no opium. Then small doses of milk or of beef tea will be cautiously given. On the eighth day the stitches will be removed.

—*Public Opinion*, March 9, says: M. Mosso, of Turin, having carried out a series of experiments with the blood of eels, finds that it possesses marked poisonous properties. Even to the tongue it has an insupportable acridity, and a very small quantity of the serum is sufficient to kill a dog. Half a cubic centimeter (about ten minims) injected beneath the skin of a dog weighing 35 pounds killed it in four minutes. At this rate, an eel weighing five pounds would contain enough poison to kill ten men. The blood of the eel, however, is inert when taken into the stomach, and it loses its toxic properties when heated.

PERISCOPE.

Intubation of the Larynx in Diphtheritic Croup.

In a communication published in the *New York Medical Journal*, March 9, Dr. Dillon Brown gives an analysis of two hundred cases of diphtheritic croup in which intubation was performed. He states at the outset that in determining the value of any operation in the treatment of diphtheritic or membranous laryngitis it is necessary to give not only the number of operations and their result, but also the whole number of such cases seen, whether operated upon or not. Again, to compare the value of any two operations in the treatment of this disease, it is not sufficient to state simply the number of recoveries following each operation; it is essential to form some idea of the character of each case and compare the result only in similar cases. The physician must take into consideration the age, the duration, and the amount of laryngeal obstruction, the presence or absence of pharyngeal or post-nasal diphtheria and its duration, the condition of the kidneys, and the presence or absence of sepsis or other complications, as pneumonia, measles, scarlet fever, whooping-cough, etc.

As regards the character of the cases, he states that nearly one-half of the patients were either absolutely hopeless or under three years of age. He has not refused to operate in a single case of advanced laryngeal obstruction, however hopeless it seemed; and besides, he has never operated until the stenosis was extreme. Not a single patient died during the operation. On the primary introduction of the tube, membrane was pushed down in several instances, but every time it was either coughed out through the tube or it followed the tube on its withdrawal. In no case was membrane pushed down in sufficient quantity to produce fatal obstruction during the operation.

Regarding the value of intubation, he says: "If those physicians who oppose intubation in favor of tracheotomy, and who have operated sufficiently often to make their opinion of any value, will give us a *complete* report of their cases—including all the cases seen, whether operated upon or not—it would be of the greatest value in comparing these operations, and would quickly consign tracheotomy to the background, for use only in special cases."

Dr. Brown says he has operated upon two hundred patients with diphtheritic or mem-

branous laryngitis, of which fifty-four, or twenty-seven per cent., recovered. The patients were divided as follows: males, 87; females, 113. The average age was 3 years 5 months; of those that died, 3 years 2 months; of those that recovered, 4 years 5 months. The urine contained albumin in 116 cases, no albumin in 15 cases, and was not examined in 69 cases. In fatal cases the average length of life after intubation was 2 days 23 hours; in cases of recovery the average time during which the tube remained in the larynx was 5 days 10 hours.

Dr. Brown then gives a tabular statement of his cases. With reference to internal medication, he says: "Since my last report in June, 1887, I have operated in one hundred and fifteen cases. Of these cases, fifty were treated without the use of bichloride of mercury, in most cases with some iron preparation; and twelve recovered, or 24 per cent. The other sixty-five cases were treated with bichloride of mercury in large doses (gr. $\frac{1}{40}$ to $\frac{1}{60}$ every hour), frequently with iron in addition to the mercury. Of these patients, twenty-four recovered, or 36.9 per cent. I am firmly convinced that the use of bichloride of mercury in the treatment of diphtheria and croup, as recommended by Professor A. Jacobi, of New York, offers us the best means of fighting this disease."

In concluding his paper Dr. Brown gives a summary of the cases of intubation hitherto reported. In this he says: "The foregoing list gives 2,368 cases, with 647 recoveries, or 27.3 per cent. It is the record of 166 operators, practising in Germany, France, England, Spain, Canada, and nearly every State in this country. The results of each operator, with twenty-six exceptions, were personally communicated to me since October 25, of this year [1888]."

Experiments with Creolin.

Some interesting experiments with creolin are mentioned in the *Wiener med. Presse*, Feb. 7, 1889. They were performed by Dr. Washbourn, of London, for the purpose of determining whether or not it is possible, without essential injury, so to saturate a living animal with creolin that the development of specific pathogenic microörganisms in it will be checked. He first proved the antiseptic and disinfecting action of the creolin in the case of microörganisms found in dead nutrients, and then, after inoculating mice and guinea pigs with virulent anthrax, he immediately injected a certain quantity of creolin in watery solution into their bellies and backs; the injection was made once or several times. The development of anthrax was checked or suppressed in this way, but only by the employment of such quantities of creolin as brought about the death of the animals of acute or chronic creolin poisoning. These experiments establish irrefutably the fact that creolin acts as a strong poison upon the animal organism. The symptoms of acute creolin poisoning consist of clonic spasms of the muscles of the trunk and extremities, which are attended with or followed by a soporose condition. In guinea pigs there was also a great increase of the secretion of tears observed. The stronger the solution of creolin injected just so much more quickly the symptoms named developed and death occurred. The injection of fifteen minims of a ten per cent. solution in mice, and seventy-five minims of a ten per cent. solution into the peritoneums of guinea pigs, produced immediate symptoms of poisoning, and death resulted at latest in a few hours. These experiments do not prejudice the employment of creolin as a local antiseptic or disinfectant.

Mode of Transmission of Measles and of Diphtheria.

At the meeting of the Société Medicale des Hôpitaux, February 22, 1889, M. Sevestre said that for a long time it was thought that measles was contagious only during and after the eruption. It is now known that it is contagious during the period of invasion of the disease, and in M. Sevestre's opinion it is especially in this period that contagion occurs. But the disease is equally contagious during the period of eruption, at least in the first days of this period, for the contagious power becomes feeble soon. M. Sevestre thinks that the atmospheric air is the habitual vehicle of the germs of measles, which are expelled with the expired air to a certain distance, especially during the spells of coughing. The reason for this opinion is that the disease is contagious from the onset of the prodromic period, when as yet there is nothing upon the skin. Again, the microbe of measles very rapidly loses its harmful property; for if healthy children are brought into a room which a child with measles has left only two or three hours, contagion will practically never occur. From this brevity of duration of its viru-

lence it necessarily follows that contagion is very rarely carried by persons or by objects.

In diphtheria, on the contrary, infection is most frequently mediate. Contagion is carried by some object, or by a sick person to a well one. Everybody is agreed upon this point. It seems also that contaminated objects preserve their virulence for a long time, even for several years.

The practical point to be learned from these facts is that patients with measles are to be isolated at once, as soon as the diagnosis is possible or even probable.

M. Graucher, however, does not think with M. Sevestre that contagion occurs from the expired air of a patient with measles, but holds that contagion is transmitted especially by soiled objects which, in turn, may infect the air. He does not deny the possibility of indirect contagion by the air, but regards its occurrence as much more rare than that by direct contact. And in accordance with his opinion as to the source of the contagion in most cases, he lays more stress upon the efficacy of disinfection. The microörganism of measles exists, according to him, in the nasal and bronchial mucus and in the tears. Contagion before the occurrence of the eruption is therefore quite natural. But he thinks that the vehicles of the contagion are linen, garments, etc., upon which the nasal and bronchial mucus, etc., have been deposited, and not the expired air of patients.—*Bulletin Médical*, February 24, 1889.

Case of Dyslexia.

L. Bruns (*Neurolog. Centralblatt*, No. 2, 1888) has observed a case of dyslexia, a condition first described by Berlin. The patient was a man 40 years old, who had had syphilis twenty years before and for seven years had repeatedly suffered with articular rheumatism. After frequent attacks of dizziness with headache and vomiting he was seized with an attack of apoplexy with subsequent left-sided hemiplegia. This improved, but soon there was a fresh apoplectic attack which was followed by a left-sided palsy; there were clonic convulsions of the right extremities. The patient died some days after the hemorrhage, and at the autopsy there was found pronounced atheroma of most of the larger cerebral arteries, as well as an area of softening in the right lens and right external capsule. Dyslexia had occurred after the first stroke: the patient was unable to proceed after reading a few words; after a short pause he was able again to read, but very soon was again obliged to stop. As regards the writing itself, that which he did spontaneously showed no variation from the normal, while on the contrary, in writing performed at dictation the patient complained that his arm became stiff and the writing altered: it resembled that observed in the case of scrivener's palsy.

Whether the dyslexia is to be regarded as a pure functional disturbance or as a group-symptom can not be decided by present experiences.—*Centralblatt f. d. med. Wissenschaften*, Jan. 26, 1889.

Use of Antipyrin for Renal Calculus.

Huchard, says the *Wiener med. Presse*, Feb. 7, 1889, has recently discovered a new property of antipyrin, which leads him to recommend it in the treatment of renal calculus. He states in the *Revue gén. de clinique et de thérapeutique*, No. 4, 1889, that he gave fifteen grains of antipyrin daily to a man who was suffering with violent renal colic. The remedy acted so favorably against the pain that the patient without asking any questions continued to take thirty grains of antipyrin daily for the next two months. The effect of this self-medication was that the pain ceased entirely, the urine, which before contained constantly sand and small stones in pretty large amounts, became clear and contained, as shown by chemical analysis, only a normal amount of uric acid. In a second case, Dr. Schweig, of Carlsruhe, states that a man 70 years old had suffered since 1870 with kidney stones, and since 1887 had taken daily three doses of one and one-half grains of antipyrin; under this treatment the pains subsided and the excretion of urates and sand markedly diminished. Huchard believes that in this second case the dose of antipyrin was too small, and that fifteen to thirty grains a day are indicated. Although these two cases are not sufficient to prove that antipyrin has a lithotriptic action, Huchard thinks they are sufficient to warrant practitioners in further experimentation. He orders the antipyrin taken during meals and adds to it, to obviate disturbance of digestion, some bicarbonate of soda, as in the following formula:

℞ Antipyrin . . . . . gr. cccxxv
Bicarbonate of soda . . . . gr. lxxv
M. Div. in pulv. No. xxx.

Sig. One or two powders at each meal.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE FOUR YEARS' COURSE.

At a meeting of the Philadelphia County Homœopathic Medical Society, April 11, 1889, a resolution was passed which heartily endorsed any movement for elevating the standard of medical education. The sentiment was pretty general in favor of a four years' optional course, provided the hundred medical colleges of the country, which have a two-year course, will mend their ways or change their curriculums, so that this State may not be discriminated against.

If this resolution is correctly reported it is one which illustrates the importance of the word "if"; for there is no likelihood of the adoption of a four years' course—optional or obligatory—by any medical school which waits until all the other schools in the United States which have a two years' course mend their ways. The argument that a compulsory four years' course for men who wish to practise in Pennsylvania will discriminate against the State is one which shows that those who use it mean by "the State" the medical schools. How the State can be the worse for having in it only thoroughly educated physicians does not yet appear. The effect on some of the schools cannot be determined in advance. So far as men intending to practise here is concerned, the legal requirement of four years of study would compel them all to study in Pennsylvania or in the schools of other States for an equal length of time. The probability is that a law such as is proposed would for a time keep Pennsylvanians in Pennsylvania medical schools, and that this would more than make up for the loss of students who expect to practise in States where the law is less exacting. At the same time, there can be no doubt that it would bring a very strong pressure to bear upon all the Eastern schools to adopt a four years' course, and as little doubt, we think, that other States would follow the example of Pennsylvania in demanding more thorough preparation of those who wish to practise medicine within their borders.

So far as we understand it, the proposed requirement is one which ought to be heartily supported, unless it can be shown that a shorter term of study is sufficient to make good physicians and surgeons, and that the conditions of this country do not warrant a step which has so much in its favor. Most of the arguments against a four years' course of study have an air of being shaped in the interest of weak and inefficient medical schools, which care more for the number of their students than for their fitness to practise. This is a matter in regard to which the community may take

a very different view, and those who expect to be practised upon may say that they will have none but well educated physicians in Pennsylvania—or any other State—and demand that the schools shall provide such physicians or go out of business.

DANGERS OF COCAINE INJECTIONS INTO THE URETHRA AND BLADDER.

The discovery of the local anæsthetic property of cocaine has proved of almost incalculable value in minor surgical operations. Perhaps no single remedy comes into play more frequently. Its use is now so common, and the evil effects from it usually so few, that there is risk of forgetting that it may act as a serious poison. It may be well, therefore, to call attention to several cases in which dangerous symptoms, and even death, have followed the employment of the remedy in what would seem at first thought to be a perfectly safe way, namely, by injection into the urethra and bladder.

One of the first recorded instances in which dangerous symptoms followed the injection of cocaine into the urethra is that mentioned by Dr. G. Frank Lydston, in the course of a clinical lecture published in the Reporter, July 28, 1888. In this case the patient had been operated on for stricture by internal urethrotomy, and a four per cent. solution of cocaine was injected every second day subsequently to facilitate the passage of the sound. On the ninth day after the urethrotomy, however, the patient in a few minutes after receiving the injection complained of dizziness, and immediately fell back in convulsions, dying in less than five minutes. Nothing abnormal was found at a *post-mortem* examination except extremely congested kidneys. It is only fair to state that Dr. Lydston did not attribute the fatal result in this case to the action of cocaine, although otherwise no adequate cause of it seems to exist. Possibly sufficient cocaine had accumulated in the system from previous injections to explain the sudden result following the last injection: the patient had received two fluid drachms of a four per cent. solution, or about five grains, at each injection.

In 1888, Dr. Simes reported, to the Philadelphia Academy of Surgery, a case in which a fatal result followed the injection into the urethra of one drachm of a twenty per cent. solution of cocaine. The patient was a man, 29 years old, and the injection was given to permit of painless internal urethrotomy. The nozzle of the syringe used in making the injection had scarcely been withdrawn from the urethra when the first symptoms appeared, and death occurred in twenty minutes from the first convulsion. It was preceded by symptoms of collapse, by convulsions, and cyanosis; the respiration especially seemed to be affected.

Still another case is reported by Stewart, in the *Medical News*, August 18, 1888, in which the injection of one and a half fluid drachms of a four per cent. solution of cocaine into the urethra, preparatory to internal urethrotomy, was followed by the appearance of collapse and clonic convulsions. In this instance there was a previous history of *petit mal*. The patient was a man 32 years old. He recovered.

Dr. Alejandro Settier, of Madrid (*British Med. Journal*, February 16, 1889) has met with a case of poisoning from the injection of cocaine into the bladder of a patient suffering with painful cystitis and chronic prostatitis. The patient had himself been in the habit of injecting from five to eight fluid drachms of a four per cent. solution into his bladder daily for seven months. When he came under Dr. Settier's care the latter injected cocaine into the bladder and followed it, after twenty minutes, with a solution of nitrate of silver. The pain was so great that the patient again injected cocaine, so that in one day he received four injections of cocaine, and, notwithstanding the fact that he was well seasoned against the drug, alarming symptoms appeared. The patient, naturally taciturn, began to talk

with great volubility. His sentences were unfinished, his speech indistinct, and his voice thick and quavering; he complained of giddiness and nausea, got up and sat down suddenly, and his gait was so unsteady that in walking he had to cling to the furniture. The tongue, mouth and fauces were quite dry, the mucous membrane blanched, the body covered with cold sweat; the pulse was small and thready, beating one hundred and five times in the minute; two or three times he vomited glairy matter. Eight hours after their onset all these symptoms disappeared, and the patient was quite well again.

At a recent meeting of the Neurological Society of Philadelphia (*Medical News*, April 6, 1889), Dr. J. Chalmers Da Costa reported four cases of poisoning from cocaine, in three of which the cocaine was injected into the urethra, and in one into the foreskin of the penis. The patients were all men; two of them were brothers, of nervous temperament and drinking habits; a third was also a drinking man, while the fourth was of nervous temperament but of unknown habits. The cases are interesting because in each the symptoms developed after a single injection, and in only one case did the quantity injected amount to as much as a grain and one-fifth (twenty minims of a six per cent. solution). In three of the cases collapse with unconsciousness soon developed, and was marked by embarrassed breathing, pale, clammy skin, dilated pupils, muscular relaxation, and general anæsthesia. This was followed by very pronounced delirium of an active type. In one case the delirium came on at once, not being preceded by collapse. The patients all recovered, and without any serious after-effects.

In attempting to estimate the part played by the cocaine in the production of the symptoms mentioned in the foregoing cases it should be recollected that operations about the genitalia give rise to shock more readily than operations in other regions; and also that in several of the cases, notably in those of Dr. Da Costa, the drinking habits of the patients and their nervous temperament predisposed them to shock. But the symptoms produced can not all be explained by the supposition that shock occurred. On the contrary, the symptoms were such as experiment has proved do actually result from the toxic effects of cocaine. The conclusion seems warranted, therefore, that while especial caution should be exercised in the employment of cocaine in urethral operations upon persons addicted to the use of alcohol or of a nervous temperament, yet its use is not to be regarded as free from danger in any persons. Moreover, the propriety of using a stronger solution than one of four or five per cent. is questionable, and so is the continued use of the remedy for local anæsthetic purposes.

RESECTION OF THE RECTUM.

In the Reporter, February 18, 1888, we described the method of resection of the rectum proposed by Kraske, which has been carried out with marked success in a number of cases. At present we call attention to a method proposed by Dr. William Levy, of Berlin, which seems to be based on sound principles, although it has never been practised upon the living. Levy's method is as follows: A transverse incision about three inches long is made over the sacrum, about a finger's breadth above the horns of the coccyx, and going down to the bone. From each end of this incision another is carried of about the same length through the skin and the whole thickness of the gluteus maximus. In one of these latter incisions a retractor is placed and drawn strongly outward. The lateral border of the ischio-sacral ligament is exposed by pushing aside the fibres of the gluteus muscle, and the greater and lesser sacro-sciatic ligaments are divided close to the horizontal incision. This operation is then repeated on the other side. The periosteum is then pushed up from the sacrum above

the transverse incision and the bone cut through with bone forceps. The flap of bone and soft parts between the three incisions is now drawn downward with a strong hook, carrying with it most of the sacro-sciatic ligaments on each side. This exposes a large part of the rectum, extending from about three-quarters of an inch above the anus to the sigmoid flexure. If necessary part of the alæ of the sacrum can now be removed, as in Kraske's method.

The remainder of Levy's method consists in removing so much of the rectum as may be necessary and any involved glands, uniting the divided ends of the rectum with a double row of sutures, replacing the flap and uniting the edges of the transverse incision with sutures of the bone and of the soft parts. The lateral incisions may be left open and tamponned with iodoform gauze, or they may be sutured except at the upper angles, leaving drainage tubes in the wound, going down to the rectum. As the patient is to lie upon his back, the drains will be in the best position for the purpose of drainage or irrigation.

The great advantage of Levy's method is that it does not interfere with the function of the outlet of the pelvis, which is robbed of its support in case part of the sacrum and the whole of the coccyx are sacrificed.

About a year ago Heineke proposed (in the *Münchener med. Wochenschrift*, 1888, No. 37) a method embodying the principles of that suggested now by Levy, but more complicated in its details, and, for this reason, less desirable. Both contemplate an improvement over any method we know of for removing morbid growths in the rectum out of reach of operations in which the bones do not have to be touched, and are deserving of the careful attention of American surgeons.

Michigan State Medical Society.—The Twenty-fourth Annual meeting of the Michigan State Medical Society will be held in Kalamazoo, Thursday and Friday, May 9 and 10, 1889, and preliminary arrangements for it are already completed.

The membership of this Society is rapidly growing, and added interest in its work is displayed from year to year, its members working together harmoniously to further the welfare of the Society. This is the first State Society to adopt the plan of division into Sections for the reading and discussion of papers, and this plan has greatly facilitated its work. Stenographers have been furnished each Section and verbatim reports of discussion are taken down. The recent volumes of Transactions shows the amount of work accomplished in this way. A similar plan will be carried out at the next meeting.

The morning sessions of the Society will be devoted to the general business meetings, the afternoons to work in the Sections.

State Medical Society of Arkansas.—A preliminary circular has been issued by Dr. L. P. Gibson, of Little Rock, Secretary of the State Medical Society of Arkansas, announcing that the fourteenth annual meeting of the Society will be held at Pine Bluff, beginning Tuesday, May 28, and lasting three days. All properly qualified physicians of the State are cordially invited to join the Society. The circular contains a list of the committees with the names of their members. A request is made that the secretaries of local societies shall send to Dr. Gibson a list of the delegates and others who will attend from their respective counties. A final circular, giving detailed information concerning railway rates, hotels, and titles of papers will be issued as soon as the necessary data can be obtained; but in the meantime Dr. Gibson will give any further information.

—The Camden County Medical Society has resolved to recommend the establishment of a State Board of Medical Examiners in New Jersey.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE RECTUM. By Wm. Allingham, F.R.C.S., Senior Surgeon to St. Mark's Hospital, etc. Edited and revised, with much additional new matter and numerous diagrams, by Herbert Wm. Allingham, F.R.C S., Surgeon to the Great Northern Central Hospital, etc. Fifth edition, 8vo, pp. xvi, 366. London: J. & A. Churchill, 1888

Allingham's work on diseases of the rectum and anus is well known, and has an established position, and this edition is likely to meet with a cordial reception. Its greatest merit is that it represents the opinions of a man who has for years devoted himself to the treatment of the diseases discussed, and who has had a very large experience. For this it must be regarded as an important contribution to the literature of the subject.

It has however certain defects. One of these is that, in this edition, it is not always clear who speaks or who is referred to—the father or the son. Another is that the latter seems to have caught his father's unfortunate style of apparently magnifying himself and slighting the experience or opinions of others. In some cases the preferences of the authors seem to be due to prejudice; in others, to sheer ignorance. The former is illustrated, we think, in their expressions in regard to Mr. Henry Smith's and Mr. Whitehead's methods of treating hemorrhoids; and the latter is conspicuous in the chapter on excision of the rectum.

As in previous editions of the book, we note that it has a miserable index. It is remarkable that our British cousins, with the many examples of good indexing which this country has furnished them, should be so slow to learn how to make this very important part of a book.

In spite of all these drawbacks the book before us is a valuable one, and is likely—as it has always done—to continue to be regarded as one of the standard works in the English language.

THE PATHOLOGY AND TREATMENT OF DISPLACEMENTS OF THE UTERUS. By Dr. B. S. Schultze, Prof of Gynecology etc., in Jena. Translated from the German by Jameson J. Macan, M.A., M.R.C.S. Eng., etc., and Edited by Arthur V. Macan, M.B., M.Ch., etc., Master of the Rotunda Hospital, Dublin. 8vo pp. xx, 378, with 120 illustrations. New York: D. Appleton & Co., 1888.

All students of gynecology will welcome the appearance of an English translation of Schultze's work. No one man has done more than he to elucidate the subjects of the normal position, or positions of the uterus, and the etiology, nature and proper treatment of the various displacements of that organ. In this book is found a complete, philosophical exposition of the subject of the displacements of the uterus, and a record of years of faithful painstaking work, by which the author has arrived at the views here set forth.

The Editor states that this book has revolutionized the opinions formerly held as to displacements of the uterus, and he predicts that the views of Schultze will eventually receive universal acceptance. This is doubtless true in the main, but in several particulars we are not prepared to believe it. In view of the many diseased Fallopian tubes which surgeons are daily removing from women suffering with pelvic inflammation, of the frequency with which they find peritonitis, and of the rarity of parametritis, we are forced to believe that Schultze attaches far too great importance to parametritis, and too little to peritonitis in the causation of displacements of the uterus. Our space forbids a consideration of the difference between the views advocated by the author, and those generally held in this country, with reference to so-called congenital anteflexion and its relation to mechanical dysmenorrhœa. Many American and English gynecologists probably will not agree with Schultze that the only pessaries which should be used are his figure-of-eight and sledge-shaped pessaries.

The author's results in the treatment of retroflexion with adhesions command our admiration. It seems probable that by following his method of separating these adhesions by bi-manual manipulation, under anæsthesia, the number of cases requiring hysterorrhaphy may be lessened. At the same time too great care in diagnosis cannot be enjoined, or else a pyosalpinx—which may be rare in Jena, since Schultze does not mention the subject, but is certainly common in this country—will sometime be ruptured inadvertently.

Features of the book specially to be commended are the excellence of the diagrammatic illustrations; and the summaries which are appended to each chapter.

The translation is a most excellent one; and the publishers have issued the book in their usual good style.

HINTS FOR TEACHERS OF PHYSIOLOGY. GUIDES FOR SCIENCE-TEACHING, NO. XIV. By H. P. Bowditch, M.D., Professor of Physiology, Harvard Med. School. 16mo., pp. 58. Boston: D. C. Heath & Co., 1889. Price, 25 cents.

This little paper-covered book contains a large number of ingenious and valuable suggestions for teaching physiology in schools. The plan proposed is such as will lead scholars to learn for themselves—to observe and generalize, instead of accepting the mere dictum of their instructors The suggestions are made in simple and practical shape, and the main topics of physiology, appropriate to school-teaching, are well covered by the distinguished author. The book is one which may be heartily commended to the notice of teachers, who will find in it an excellent outline of instruction and illustration; and it would be a great help to parents who have some knowledge of physiology themselves and wish to give their children information in regard to this important branch of science

RECTAL AND ANAL SURGERY. By Edmund Andrews, M.D., LL.D., Professor of Clinical Surgery in the Chicago Medical College, etc., and E. Wyllys Andrews, A.M., M.D., Adjunct Professor of Surgery in the Chicago Medical College, etc. Illustrated. Second edition, revised and enlarged. Large 8vo, pp. xiv, 140. Chicago: W. T. Keener, 1889. Price, $1.50.

In noticing the first edition of this book, Nov. 26, 1887, we spoke of its admirable character and especially of its interesting protest against the folly and fraud of certain quacks who chiefly infest the Western States. The new edition has all the merits of its predecessor, and has been revised and enlarged so as to cover a little more ground than this did.

It is a book full of practical common sense, without being too elaborate, and will, we have no doubt, enjoy even a larger popularity than the first edition did.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

247. The Technique of Ovariotomy, as Practiced at the University Hospital by Prof. Goodell. By Lewis H. Adler, Jr., M.D., Philadelphia. From the *Medical News*, Dec. 29, 1888.

248. Die Verbreitung der Tuberkelbacillen ausserhalb des Körpers. von Dr. Georg Cornet, prakt. Arzt in Berlin und Reichenhall. (From *Zeitschrift für Hygiene*, Vol. v, 1888.) 140 pages

249. Ueber das Verhalten der Tuberkelbacillus in thierischen Organismus unter dem Einfluss entwickelungshemmender Stoffe. von Dr. George Cornet, prakt. Arzt in Berlin und Reichenhall. (From *Zeitschrift für Hygiene*, Vol. v, 1888.) 33 pages.

247. This is a pamphlet which ought to be in the hands of all who have purchased Goodell's Lessons in Gynecology; because Dr. Goodell has modified his methods of preparatory and after treatment, as well as of operating, in very important ways since the last edition of his book was published. The article by Dr. Adler represents his present views and practice, and is both interesting and instructive.

248. This reprint treats of the distribution of the tubercle bacilli outside of the animal body, and is marked with a thoroughness which is a credit to its author. It assumes that the bacillus is the exclusive cause of tuberculosis, and then proceeds to prove by a large number of inoculation experiments that it is everywhere present in the surroundings of phthisical patients. But, if the bacillus is so ubiquitous, why should it be so difficult to infect animals by compelling them to inhale tubercular virus, or why should so infinitely few persons, who are exposed to it, contract tuberculosis? This incongruity is fully recognized by the author, but it is a question whether his theory of unequal distribution of the bacillus will account for it. His pamphlet will well reward careful perusal.

249. This is an effort to show the influence of germicides on the tubercle bacilli within the organism. The animals are infected, the medicament introduced, and with the usual result of the bacilli coming out of the contest with flying colors. The principal agents which were employed for this purpose were tannin, lead acetate, hydrogen sulphide, menthol, acid sublimate, and creasote. The mountain cure of Davos was also tested on six animals, with lamentable results. The pamphlet is valuable in showing to what desperate efforts those are driven who base their faith of curing tuberculosis on the hope that they may discover something which will annihilate the bacillus.

Literary Notes.

—*The St. Louis Polyclinic* is the title of a new monthly magazine edited by L. A. Turnbull, M.D., in the interest of the St. Louis Post-Graduate School of Medicine. The first (April) number contains twenty-eight octavo pages of reading matter, and eight pages of advertisements and reading notices. Subscription price, one dollar a year.

Notes and Comments.

Methods of Instruction in Medicine.

Dr. J. West Roosevelt speaks as follows in a paper on medical education, published in the *N. Y. Med. Journal*, March 16, 1889: Preliminary education is beginning to receive some of the attention it deserves. It is well to consider what is the best training for one who intends to study medicine. Let me avoid starting the old discussion of the relative value of classics or mathematics. It seems to me that, if it really be necessary to "train the mind" by the study of some language in the irritating and complicated way so long the fashion among teachers of Latin and Greek, German might be made quite as dull, quite as involved and complex as Latin. When the student finishes the "training process" he will end with a more or less confused notion of a language which he must use and can learn perhaps more easily because of the training. I am not speaking of the rational teaching of Latin and Greek, merely of the method of lifeless drill in grammar so long in vogue.

Let us suppose that a student has a fair general education; what does he need to prepare for medical studies? Surely the answer should be: Special training in some branch of science requiring observation, classification, and more or less delicate use of the hands and special senses. It does not make much difference what is selected—chemistry, botany, comparative anatomy, or any other. Whatever it be, let the student learn it not from a book alone, but let him do practical work. This does not preclude a good education in other matters; in fact, it presupposes such an education.

Perhaps the greatest need in medical education is some method for teaching teachers. It is almost unavoidable that medical instructors should go to work in an amateurish sort of way. Teaching to them is a small part of their aim in life. Most men really are practitioners first and teachers afterward. Many seek to teach merely because they can thereby advance their private practice. This is natural, as instructors are poorly paid. Unfortunately, many men teach without having the faintest idea of the difficulties of so doing.

It is not only necessary that a teacher should know his subject. He should also know precisely what he wishes to teach about it. He should appreciate the difficulties likely to trouble his pupils. He should cultivate the faculty of expressing

himself clearly and concisely. Should be on the lookout for illustrations and similes. Above all, he should try to learn how to make his pupils think for themselves. As in all educational institutions, so in medical schools, the greatest object should be to show *how* work is done.

Schoolroom Space.

Mr. H. Courthope Bowen, whose opinions on all matters connected with the proper construction of schoolrooms are entitled to great weight, and are regarded as authoritative by the leading medical journals of England, expresses somewhat as follows what, in his judgment, should be considered a good schoolroom. Taking the case of a room 14 feet high, fairly ventilated and always well aired in recess, he would assign two-thirds of the floor-space to the scholars and their desks, and keep the other third for the teacher, the blackboard, etc. With single desks, 22 inches should be allowed from side to side, and 3 feet from back to front, for each scholar. The passages need not be more than 18 inches for those running from back to front, and 1 foot for those running from side to side. In such arrangement, counting the passages, each scholar has (without reckoning the share of the space allotted to the teacher) a trifle more than 40 inches from side to side, and just 4 feet from back to front. In a room 25 feet by 20 feet the floor-space for scholars' desks will be 16 feet by 20 feet, with 4 feet from back to front per row, and accommodation is provided for 20 scholars. The whole floor-space is 500 square feet, and the cubic contents of the room 7,000 cubic feet, with 20 square feet and 280 cubic feet per person.—*Science*, April 12, 1889.

Amputation of the Penis.

The most unpleasant symptom following amputation of the penis is the funnel like retraction of the urethra, which causes the patient endless discomfort. Dr. Assaky, of Beucharest, says the *Centralblatt für Chirurgie*, March 30, 1889, overcomes this by dissecting the pars spongiosa of the urethra from the penis for about an inch beyond the superficial incision. Then the corpora cavernosa of the penis are cut through from below, leaving about a half inch of the urethra protruding beyond. The tunica albuginea and the skin are then brought over the stump of the pars cavernosa and stitched around the protruding urethra. This will retract to some extent leaving a very natural looking meatus.

A Doctor's Presence of Mind.

The Philadelphia *Ledger*, April 19, says that the superintendent of a private asylum in Russia (so the story runs) lately had complaints laid before him by one of the patients, who was considered convalescent, as to the poor quality of food which was given, especially the soup, which he stated was half water. The doctor, thinking it was not unlikely that the cooks took advantage of the weak intellects of the patients to tamper with the food, and acting upon the suggestion of the man who had laid his complaint in a very coherent manner, at once proceeded to the kitchen to inspect the soup which was boiling in a huge cauldron over the fire. He lifted the lid, and was about to take out a small quantity to test it, when he was startled by the patient, who had followed him into the kitchen, whispering in his ear, "Do you know, doctor, you are so nice and fat, you would make good strong broth." The man then seized him by the shoulders, preparatory to throwing him into the cauldron. The doctor knew that it would be useless to struggle with the lunatic, who was tall and powerful. With great presence of mind he said quietly, "I quite agree with you, it is an excellent idea, but I fear my clothes will spoil the flavor of the soup. Let me first go and take them off." The madman seemed to see the force of this reasonable request, and permitted the doctor to leave the kitchen. By this means the latter was able to call for assistance and have the man placed under arrest.

Hyperidrosis among Soldiers.

An official circular addressed to Prussian army surgeons, respecting excessive sweating of the feet and other parts in the soldiers as an affection demanding treatment, advises the use of chromic acid—of the strength of one part in ten of water—as an efficient and economical application. In cases of hyperidrosis of the feet, such a ten-per-cent. solution, applied at intervals of three, four, or six weeks, has proved sufficiently strong to remedy this source of disability. From the point of view of military hygiene, the prophylaxis of this affection is not merely a question of discomfort and inconvenience, but has its relations to the efficiency of the service, since all soldiers having hyperidrosis will be more or less prone to recurrent catarrhal troubles and to the evils attendant thereon. Hyperidrosis of the feet, moreover, impairs the marching capabilities of the men.—*New York Med. Journal*, April 20, 1889.

Sulphur Fumigation.

Fumigation by the burning of sulphur is the most common method employed by boards of health in the disinfection of apartments in which contagious disease has existed, and the clothing worn by the patients during their illness. In an address delivered by the distinguished chemist, Dr. E. R. Squibb, before the Kings County Medical Association, he called attention to the fact that there must always be an abundance of watery vapor in the room to be disinfected; otherwise the sulphurous-acid gas generated by the burning of the sulphur is not an efficient disinfectant. The same is true of chlorine gas when used for disinfecting purposes.—*Science*, April 12, 1889.

Treatment of Variola with Cocaine.

Dr. E. Ory recommends (*Revue gén. de clin. et de thér.* No. 9) the treatment of variola and varioloid with cocaine. In a case of severe confluent varioloid (*sic*) immediate improvement occurred and the eruption quickly subsided after the patient had taken during the night more than one-third of a grain of cocaine. After some days ten drops of a four per cent. solution of hydrochlorate of cocaine were ordered four times daily, and in less than ten days the patient was cured. In a second case of variola recovery resulted under the cocaine treatment five days after the appearance of the pustules. A third patient with very severe hemorrhagic variola recovered without scarring in five days under the cocaine treatment. Two children likewise recovered from varioloid in five and six days respectively under the same treatment.

Ory gives to adults ten drops of a five per cent. solution of hydrochlorate of cocaine four times daily, to children he gives eight drops of a one per cent. solution four times a day. As in all cases the vesicles dried immediately after the employment of the cocaine, it cannot be positively declared that the disease was variola. Ory believes that as the cocaine so quickly neutralized the virus of variola in the infected organism it may check the development of it; and acting upon this belief he recommends its employment as a preventive remedy to be used by those persons about patients with variola.

The above account of Ory's employment of cocaine in variola and varioloid is taken from the *Wiener med. Presse*, March 17, 1889. If the results obtained by other clinicians are approximately as favorable as his, cocaine will prove to be an astonishingly valuable remedy. It should not be difficult, with small-pox widely distributed over this country as it has been during the past winter, to determine with certainty just how much credence is to be given to Ory's observations.

Oxychloride of Mercury as an Antiseptic.

At the meeting of the Ophthalmological Society, of Paris, Feb. 5, M. Chibret stated the following conclusions as the result of his bacteriological researches:

1. The micrococcus pyogenes aureus may be met in the normal human conjunctival sac. However rare, its presence may be expected.

2. Its presence at the time of an operation for cataract is, besides, compatible with a normal cicatrization.

3. Bathing the eyes with oxychloride of mercury 1 to 1500, for five or ten minutes during three days, seems to insure antisepsis better than irrigations.—*Bulletin Médical*, Feb. 10, 1889.

Bryonia Alba in Hemorrhage.

Petresca of Beucharest has been experimenting with the root of bryonia alba, and he finds, according to the *Berliner klin. Wochenschrift*, February 25, 1889, that it is an especially active hemostatic. He employs a decoction of twenty to twenty-five parts of bryonia root to three hundred parts water, reduced to 150 parts, then filtered. It is mixed with syrup, divided in four parts and taken every half-hour. He has also investigated the glucoside "breïn," contained in bryonia. The watery and alcholic extracts, in doses of from fifteen to forty-five grains a day, have proved very useful in metrorrhagia, hematuria, hemoptysis and epistaxis.

Cystitis in Women.

Dr. Thomas Moore Madden, of Dublin, treats severe cystitis in women by dilatation of the urethra. This permits a continuous outflow of the secretions. In many cases this treatment, together with mild washing of the bladder, will effect a speedy cure. If not, the fundus and neck of the bladder should be wiped off with a tampon of cotton soaked in carbolized glycerine, and inserted through the dilated urethra. The use of cocaine will relieve all pain caused by this operation.

Salol in the Treatment of Burns.

Two Italian physicians, Fato and Cabatelli highly recommend salol in the treatment of burns. They first wash the burned part carefully, then empty the blebs and apply small pieces of linen spread with the following ointment:

Lanolin	100 parts.
Salol	3 parts.

This dressing, renewed two or three times a day, rapidly allays the pain, the authors say, prevents inflammatory reaction, and allows rapid healing to take place without bad scars.—*Bulletin Médical*, Feb. 10, 1889.

Influence of Chronic Lead Poisoning on Pregnant Women.

The Paris correspondent of the *Therapeutic Gazette*, March, 1889, says that the influence of chronic lead poisoning on pregnant women and the fœtus was brought to light in 1860 and 1861 by Dr. Constantin Paul. A new instance, interesting on account of the thoroughness of the observation, has just been related to Drs. Hermann-Legrand and Winter of Paris. It occurred as follows: The patient, a woman, 27 years old, worked as a compositor in a printing establishment. She had six times been to the hospital before for lead colic. Five previous pregnancies resulted four times in abortion, and once in a full-term child, which died of convulsions seven months afterward. On the present occasion the patient entered Dr. Budin's service at the Charité Hospital, pregnant for the sixth time, and seven and a half months advanced. She recently suffered again from lead colic, and presented the usual symptoms of the poisoning. Three days after her reception she gave premature birth to a child, but recovered without accident. The husband, it should be added, is a compositor, also affected now and then with the lead-symptoms, but never to any serious extent; no syphilitic taint was observed in him, but a little alcoholism. The child, a boy, was puny, ashy-pale, weighed ten hundred and twenty grammes (about thirty-five ounces avoirdupois), and died after fifteen days. At the autopsy, besides the peculiar appearance and dwarfish size of the kidneys, and a cirrhosis of the liver, the remarkable point was the presence of considerable quantities of lead in the hepatic parenchyma. None was found in the kidneys; they had evidently been impeded in their development, but held no lead. This observation demonstrated that one of the most insoluble of poisons may be transmitted from mother to fœtus, and cause in the child's organs lesions sufficient to render them unfit to carry on life. This much so far may readily be taken for granted, as it is supported by clear evidence. But Drs. Hermann-Legrand and Winter go further, on ground scarcely solid enough. They think that besides hereditary saturnism, there exists quite a series of similar poisonings, not only mineral but also organic, and even bacteriological in their origin. For the present it seems safer to stop at lead, and, so far as other hereditary poisonings are concerned, to wait for further developments.

Adulterated Milk.

The Philadelphia *Ledger*, April 18, says that the Board of Health has adopted a report of its Sanitary Committee asking the City Councils of Philadelphia to pass an ordinance, framed under the provisions of the act of Assembly of April 20, 1869, "to prohibit the sale of adulterated or impure milk in the city of Philadelphia." The ordinance comprises ten sections, the first of which prohibits the sale, under penalty, of milk which is offered as a pure article but has had any part of the cream removed, or which has been in any way adulterated. The second section permits the sale of skimmed milk, on condition that the vessels containing it are so marked in letters not less than two inches in length. The third section prohibits the sale of skimmed milk as such when it contains less than nine per cent. of the milk solids, exclusive of butter fat. In Section 4 it is made a punishable offence to sell impure or adulterated milk; to keep cows in a crowded or unhealthy condition, or feed them upon food of an unwholesome nature. Section 5 declares the addition of water to milk to be an adulteration; also, milk obtained from cows fed on distillery water or other unwholesome food; or from cows kept in a contaminated atmosphere, or from tuberculous cows. Section 6 provides that, for the purposes of prosecution under the ordinance, milk shown by analysis to contain more than 88 per cent. of watery fluids, or less than 12 per cent. of milk solids, or less than nine per cent. of milk solids exclusive of butter fat, shall be considered to be adulterated. Section 7 fixes a penalty of $50 for the first and $100 for the second and subsequent offences. The remaining sections of the ordinance provide for its proper enforcement.

Dried Potato.

In the *Voënno-Sanitarnoïë Dëlo*, Dr. Jakov M. Shmulevitch emphatically draws attention to dried potato as an important food-article, possessing some very valuable advantages in comparison with the vegetable in a fresh state. The advantages claimed for the article are these: (1) while fresh potatoes easily rot, blacken, and sprout, dried potatoes, when kept duly protected from moisture, remain in the best condition for a very long time; and (2), being by far lighter and less bulky than fresh potatoes, are by far more convenient for preservation and transportation, which point has a great practical importance, especially in time of war. To be fit for culinary use, the article requires a preliminary maceration in water for about ten or twelve hours.—*Science*, April 12, 1889.

The Suppression of Small-Pox.

An outbreak of small-pox is reported to have occurred recently in Minneapolis, and the health-officer of that city is credited with having summarily and successfully dealt with it. According to *The Journal of the American Medical Association*, as soon as a case was announced, a consultation was called to determine if the disease was small-pox. That being settled, the patient was removed to the quarantine hospital for treatment. The house where he lived was quarantined, and all the people directly exposed were confined in it. Dr. Kilvington's assistants then began to look up all people indirectly exposed, and vaccinated them. Quarantine houses had guards stationed about them, who allowed no one to go in or out during the season of quarantine. The quarantine people were vaccinated, and during the time until it could be determined whether the vaccination would take, they were supplied with food. When the vaccination took, the person under quarantine was bathed, given new clothing in the place of the old, which was burned, and he was then discharged. When a house had been emptied of people under quarantine, the bedding and curtains were burned, sulphur burned in all the rooms, and the walls sprayed with corrosive sublimate. None of the inspectors or guards were allowed to enter any of the houses under quarantine, when there was danger; and *the doctors that did the vaccinating saturated their clothing with the corrosive sublimate before and after entering a house where there had been small-pox.* The clothing and bedding were either paid for at a reasonable price by the board of health, or were replaced by new articles. In one of the houses quarantined, *there were 31 laboring men who were inclined to object to the rules of quarantine.* One escaped, but he was taken back when found, *and a guard, with a rifle and instructions to shoot* should he attempt to escape, was put over him. Since Jan. 13, six thousand people have been vaccinated, and the schools, public and private, have been systematically visited, and unvaccinated children vaccinated.

The absurdity of saturating the clothing of the vaccinators before and after entering each house where there had been small-pox is self-evident. Nor do we believe that in this enlightened age any guard would be instructed by a health-officer to shoot a laboring man who, after being shut up forcibly in a house where a case of small-pox had been, should attempt to escape, especially when the house had been disinfected, and the man himself vaccinated. The account above given must, we think, have been obtained from some source outside the health-office of Minneapolis.—*Science*, April 12, 1889.

The Ritual of Circumcision.

Circumcision, says Dr. Messala Pogorelsky, in the *Centralblatt für Chirurgie*, March 30, 1889, is not only practiced by the Jews and Mohamedans, but also among many tribes and nations of America, Asia, Polynesia and especially in Africa, where, as in Abyssinia, for instance, the custom is also in vogue among the Christians. In Central and South Africa not only the men are circumcised but also the women, in whom the labia minora are cut away. Professional circumcisers go from town to town offering their services to the people.

The ritual of circumcision was originally practiced by the Jews for hygienic reasons. The Christians gradually dropped the practice; those in Rome being the first to do so. Their reasons for abandoning the ritual were principally to make a distinction between themselves and the Jews, and also because they considered the right a hindrance to the spreading of Christianity.

From a surgical point of view, the operation is of great importance. Erichsen says, "all children born with phimosis should be circumcised, also those with an abnormally long prepuce, even if phimosis does not exist. The operation promotes health, cleanliness and propriety, and it would be well if we were to make its prac-

tice universal." Pogorelsky believes that many barren marriages are due solely to phimosis, and points out the dangers of paraphimosis, retention and the formation of stone, as the possible results of phimosis. Sayre speaks of its causing reflex paralysis and contractions of the lower extremities.

Erichsen quotes many spasmodic diseases as arising from infantile phimosis. Thomas cites 16 cases of trismus neonatorum which were cured by circumcision. Adams cured a case of nocturnal emission by the same operation. It has also proved itself of value in hypochondriac subjects and in cases of chorea minor, neuralgia, hysteria, hallucination and paresis.

Michigan State Medical Society.

Committees of the different sections of the Michigan State Medical Society urgently desire that members further the work of the Society by contributing brief papers. Those willing to do so are requested to fill out a blank, to be furnished by the Secretary, and return it by mail to the Secretary of the Section before which the paper is to appear. Papers should not exceed twenty minutes in length. Those presented must be fully completed, that the publication of the Transactions may not be retarded.

Applications for membership may be filled out by any regular physician desiring membership in the Society. They must be presented by the applicant in person at the annual meeting. Railroad certificates for reduced fare will be sent to all physicians, other than members, who desire them, on application to the Secretary.

The headquarters of the Society will be at the Burdick House, Kalamazoo. All Sessions of the Society will be held in the 1st Presbyterian Church, corner of Rose and South Streets. The Officers of the Society solicit the coöperation of all members, to the end that the next meeting at Kalamazoo may prove the largest and most successful in the history of the Society. The President of the Society is S. S. French, M.D., Battle Creek; and the Secretary is Geo. Duffield, M.D., 25 Washington Avenue, Detroit. The Secretaries of Sections are: Practice of Medicine, H. B. Hemenway, M.D., 524 South Park St., Kalamazoo; Surgery, F. W. Mann, M.D., 250 West Fort St., Detroit; Obstetrics and Gynecology, C. Henri Leonard, M.D., 18 John R. St., Detroit.

NEWS.

—It is stated that cholera is epidemic in the Philippine Islands, and that out of 1,500 cases, 1000 have proved fatal.

—Mr. Henry C. Gibson has given $2500 toward establishing a Chair in the Department of Hygiene of the University of Pennsylvania.

—The Shelby County (Indiana) Medical Society held an interesting meeting at Shelbyville April 9. The morning session was taken up with scientific discussions, and in the afternoon the members and invited guests sat down to a banquet.

—Dr. Sutton, of Pittsburgh, has just finished a series of 50 abdominal sections for diseased ovaries. In the 50 cases he has had 3 deaths. Of the last 36 cases, only 1 was fatal, and in the last 30 there were no deaths. Many of the cysts were very large and adherent.

—According to the *Berliner klinische Wochenblatt*, March 25, Berlin is becoming a healthier city. Although the increase of population was 3.68 per cent. greater last year than the year before, statistics show 32,086 deaths this year against 36,003 the year before. A notable feature is the great decrease in the mortality of children.

—The *Lancet*, March 23, states that the third obstetric clinic at the Vienna Hospital, the director of which is Dr. G. Braun, has had to be closed on account of the occurrence of an epidemic of puerperal fever. This is believed to be due, not to any want of antiseptic precautions, but to the unsatisfactory hygienic condition of the building, which is old, and in which there have been repeated epidemics of puerperal fever.

—The *Deutsche med. Wochenschrift*, Jan. 31, 1889, says that the number of physicians in Germany has so greatly increased in recent years as to have more than doubled since 1880–81. For the examination year 1887–88, according to the publication of the Chancellor, there were 1215 physicians, 562 of whom were in Prussia and the rest scattered throughout the other German States. The numbers of dentists, veterinarians and pharmacists have also increased.

—The Commission appointed by Commissioner Coleman to investigate the subject of hog cholera has nearly completed its work, but finds that additional time will

be necessary to finish the report, which was expected April 1. Secretary Rusk has extended the time 30 days. The Commission consists of Dr. Shakespeare, of Philadelphia; Prof. Bolton, of Columbia, S. C., and Prof. Burrill, of Champaign, Ill. The Commissioners have been pursuing their investigations independently for the past five months, but have met from time to time for conference.

HUMOR.

MAN IS ABOUT the only animal who "draws in his horns" through his mouth.—*Danesville Breeze.*

TEACHER—"Now, children, I will give you three words: Boys, bees, and bears; and I want you to compose a sentence which will include all three words."

Small boy—"I have it."

Teacher—"Johnny McCarthy, you may give us your sentence."

Johnny McCarthy—"Boys bees bare whin they goes in swimmin'."—*Harper's Bazar.*

DOCTOR—"Well, there's only one thing for you to do—you must go yachting for nine months!"

Patient—"Oh, that costs so much money; besides I'm a bad sailor—is there no alternative?"

Doctor—"Well, yes—by no means an expensive one, nor one that will make you sick. Don't eat so much!" (Patient chooses the yacht.)—*London Punch.*

THE LAST THE WORST.—Dullard—"So old man Richly is dead at last."

Brightly—"I wonder he lived so long, with all the doctors. Why, Dr. Scalpel had a hack at him, Dr. Piller had a hack at him, and a dozen others."

Dullard—"And now the undertaker has him."

Brightly—"Yes, by gum! and he's the worst. He got seven hacks and a hearse at him."—*Lowell Citizen.*

DANGEROUS TITLES.—Pedestrian (to Washington Policeman)—"What is the meaning of this great crowd in the street, officer? Is anybody hurt?"

"No; there has been an accident and the street is blockaded, but things will soon be in shape again."

"But tell me what has happened."

"Why, you see, Vice President-elect Morton has just met First Assistant Postmaster General Stevenson, and their titles are too long to pass each other on the same thoroughfare. We are trying to induce the First Assistant Postmaster General to resign for half an hour while we get things in shape."—*Chicago News.*

A TRUE MORAL DISTINCTION.—"James," said the grocer, as he looked up from the morning paper, "they have begun to make maple sugar in Vermont already."

"Yes, sir," said the clerk, with ready comprehension. "Those maple sugar bricks left over from last year are down cellar. I'll have them sandpapered and put in the front window to-morrow morning."

"Have you the same sign you had last year to stick up in the box?"

"Yes. It reads 'Fresh from Vermont, strictly pure.'"

"You may use that sign again, James. I don't think it would be exactly right to paint a new one with that inscription."—*Chicago Tribune.*

AN ARTICLE which lately appeared in the *Lancet*, in relation to doctors who tried to appear very learned by using high-sounding technical words to their audiences, suggests to one of our readers an anecdote of the late Dr. Physick. Two doctors had a case of a rather obscure and obstinate character. Dr. Physick was requested to join them in consultation. On his arrival one of the doctors jumped up and began in high-toned and abstruse words to explain the case to Dr. Physick. In the course of his address he said: "Moreover we at last tried to act on the man's dermoid capillaries." This was more than Dr. Physick could stand, and he impatiently broke in and said: "Doctor, for mercy sake, as I have no medical dictionary with me, please explain. Do you mean to say that you tried to sweat the man?"

OBITUARY.

J. H. KIDDER, M.D.

Dr. J. H. Kidder, of the Smithsonian Institution, died in Washington, D. C., April 8, of pneumonia. Dr. Kidder served as a surgeon in the navy until about twelve years ago, when he resigned and became connected with the scientific branch of the Government service. Under Professor Baird he was connected with the Fish Commission, and during recent years was Director of the International Exchanges in the Smithsonian Institution. He leaves a wife and three children.

WHOLE No. 1679.] MAY 4, 1889. [VOL. LX, No. 18.

PRICE, $5.00 PER YEAR. SINGLE NUMBERS, 10 CENTS. ESTABLISHED IN 1853, BY S. W. BUTLER, M.D.

THE MEDICAL AND SURGICAL REPORTER

A WEEKLY JOURNAL

LIBRARY SMITHSONIAN MAY 6 1889

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER,
N. E. COR. 13th & WALNUT STS., PHILADELPHIA.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

NOW READY.

Leidy's Treatise on Human Anatomy.

New (Second) Edition, Rewritten and Enlarged. Containing 495 Illustrations.

By JOSEPH LEIDY, M.D., Professor of Anatomy in the University of Pennsylvania, etc., etc., 8vo. Extra cloth. $6.00. Sheep. $6.50.

As most of the recent text-books of anatomy are very cumbersome, the condensation of this volume is a feature of great merit. The first edition of the work, which has been out of print for many years, was very highly esteemed, and old copies have long commanded extravagant prices. The present edition (entirely rewritten) presents the ripe fruits of Dr. Leidy's experience of many years of successful labor as a teacher and as an original observer and discoverer in anatomical science, and the work will be everywhere recognized as the leading authority on the subjects of which it treats.

DISEASES AND INJURIES OF THE EAR:

Their Prevention and Cure. Volume V. of PRACTICAL LESSONS IN NURSING. By CHARLES H. BURNETT, A.M., M.D., Consulting Aurist to the Pennsylvania Institution for the Deaf and Dumb, Philadelphia, etc. 12mo. Cloth. $1.00.

The previous volumes of this series have all been received with a marked degree of favor, not only by the physician, but by all who are interested in the careful nursing of the sick. The present volume is edited and prepared in such a manner that all who read it will be able to gather much profitable information.

*** For sale by all Booksellers, or will be sent by mail, post-paid, on receipt of price.

J. B. LIPPINCOTT COMPANY,
715 and 717 Market St., Philadelphia.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO.,

PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

Clinical Lecture.

ABASIA FOLLOWING POISONING WITH CARBONIC OXIDE.

BY PROF. J. M. CHARCOT, M.D.,
PARIS, FRANCE.

Gentlemen: The case that I present to you to-day is one that is worthy of attention, as it is rare and of a kind but little known. The affection with which the patient is attacked came on after asphyxia from carbonic oxide. The question arises here, does his trouble depend entirely upon the poisoning or on something else? You will remember that certain cases of poisoning have special relations with the nervous system; and you know the effects that often follow lead poisoning, as well as that from alcohol. This morbid state appears sometimes not to merit the denomination of toxic hysteria, but simply tends to provoke certain disorders such as I think you will find in the case before us.

This man, as you see, seems to be vigorous, notwithstanding that he is a little pale and depressed. He has a nervous heredity and a history of acute nervous trouble in the past, which I will not speak of at present. He presents certain symptoms to which I wish to call your attention. I have had him placed on a bed, although he can stand up, for I wish you to remark that, when lying down, he is in an absolutely normal state and does not present any signs of dynamic or organic affection. His inferior members are supple and he can make all the movements that I ask him to do: he raises his legs, gives a kick, resists all efforts I make to bend the limbs or stretch them, so that coördination is perfect. Sensibility is also good, and the patellar reflex is normal. In a word, there is no paraplegia and no ataxia. The general movements of the body are also normal, as he can turn easily on his back or front; he can also make the motion of swimming—*he knows how to swim, and has not forgotten it;* just notice that fact: when he is sitting it is the same, and when he rises we do not see anything abnormal; for he can stand

still with his legs together, or when they are divided, or when in the position for fencing. But, you will ask, what is the matter with him then as he seems to coördinate all movements well? The moment I order him to walk the special incoördination of his case is shown; you will see a series of flexions and extensions of a rapid character which constitute a most singular method of walking. He can hardly turn and cannot walk backward to save him. Notice the way he starts, and this will allow us to analyze the trembling method of stamping or kicking about that he makes as he walks.

You know that in normal walking we commence by bending the knee, and then we raise the foot. Our patient tries to bend the knee also, but at that moment a contrary movement of extension seems to come over him, and he tremblingly lifts his foot from the ground and gives us the spasmodic trembling movement of paraplegia—which we know that he has not, however; we might define the movement by supposing a paraplegic patient who had at the same time a spinal trembling movement. This anomaly, which appears when he starts to walk, continues and increases if he continues to walk, and he goes on like an automaton, bent forward. There is a sort of rhythm in his incoördination which resembles rhythmical chorea, as Professor Grasset, of Montpellier, showed in a similar case; but this is only on appearance, as chorea of the rhythmic form comes not only while the patient is walking but also during repose; besides, it is involuntary, the patient has no power to stop the movements, while our patient has only to stop his movements when he likes.

This man then *does not know how to walk any more*, and does not present any incoördination except for that mode of progression and for that only. Certainly you can understand, *a priori*, that the different methods of progression, such as walking, jumping, dancing, swimming, etc., are quite independent of each other. And when I tell the patient to jump with his feet joined, he can do it. Well, this is explained by the fact that these movements are learned and can be unlearned. A child is born with the single predisposition to execute movements of walking, and to succeed in the regular production of this act he has to make a long apprenticeship. The memory of the movements needed to walk are represented in the cerebral shell by a cellular group that is quite distinct from that which corresponds to dancing and also from that of swimming. I have shown you that the mechanism of swimming in our patient is intact, he has only interference with walking in a natural way.

I remember the case of a little boy, who could not walk but could jump about the garden of the establishment in which he was under treatment. This peculiarity is curious because it is unforeseen; but it is only a physiological demonstration of the fact that the mechanisms of the different methods of progression are isolated, and independent of each other. I compare the different cellular associations which in the medulla preside over the different modes of progression, to the rollers of an organ or of a music box. The combinations of little points on the rollers, you know, correspond to certain musical tunes or airs. The brain, in my comparison, plays the part of the strings that work the organ, to play or not, and to change the air or to stop it. In our patient the roller of walking is affected, so that there is a contrast between the movements of flexion and extension to the profit of the last; and apart from ordinary regular walking our patient can make any other movement. If he wishes to stride, as actors do in dramatic pieces, he can do so. And you can see him in the garden striding about like a tragedian. Another peculiarity is that he does not turn around like other people, but makes the "right about" of the soldiers. So that he can do almost anything except walk.

There is really nothing curious in nature, it is only our ignorance of these facts that makes things seem so. The first time I ever saw a phenomenon of this kind was in a little boy who was sent to me from Havre, and I was much surprised. He had developed his attack from fear at being charged to make a little speech to the superintendent of his school, who was visiting the house. The fact of having to speak before him, was enough to make this sensitive child ill, and two days afterward he could not walk. When I saw the little patient he was in his bed; he could make all the regular movements, and sensibility was intact, as well as the patellar reflex. On trying to make him stand up it was found that he could not do so, but fell to the ground, so that he could neither walk nor stand. When he got a little better he could jump up a tree and climb, but did not walk for some time. After a relapse he was cured finally.

I have known this affection only for a few years, and I think the first work that was

published upon it was in 1883. With M. Richer, I called it a special form of motor impotency of the inferior members, owing to the want of relative coördination of standing and walking; but I wish to say that we found in a work of Dr. Jaccoud's, entitled "Paraplegia and Ataxia of Movement," a passage that briefly spoke of the defect of automatic movement. The author said: "The movements are normal when they are made in the sitting or lying posture, and become ataxic only when the patient stands or walks." M. Jaccoud thought that it was a reflex that came into action when the foot was put upon the ground; but this interpretation does not seem to be well founded. If his theory is not exact, the description of the affection was good. Besides this description, I found in a work by Weir Mitchell, published in 1885, a description which shows that this author has seen the disease also. Under the name of *hysteric ataxia* Dr. Mitchell gives two forms of it: one in which the trouble depends on anæsthesia, as Briquet and Laségue also saw; and a second form that he describes thus: "The patient has the free use of his legs when he is lying down, but when standing or kneeling the incoördination is at once manifest," etc. The disease then is called now *Astasia-Abasia;* and you will find all that relates to it in a complete work by a former interne of mine, M. Blocq. I have seen several new cases since, and Professor Grasset is about to publish an account of one in the *Montpellier Médical.*

This then is the history of abasia. I have already told you that it attacks young people, but adults are not entirely exempt from it, as our present patient is 41 years of age. It gets well, as a rule, unless it is complicated with organic trouble. In our case it is dynamic in nature, and I was even afraid the patient would be well before I could present him to the class.[1]

The description of abasia has another point that I must speak of. You must not imagine that it is always the same in its symptoms. There are different forms; for instance, my first patient could neither stand nor walk; the moment he was put on his feet, he fell. This form might be called paralytic. A second variety contains cases in which standing and walking of a kind are possible, but the walking is quite abnormal. One of my patients, whose history was published by Miliotti, was a type of this class. When lying down or sitting his movements were normal, but on standing the contortions commenced; his thighs bent on his legs, and the trunk on the pelvis; then he straightened up only to fall again. In his case it was the reverse of the condition of our present patient, for flexion was increased instead of extension. In other abasic patients the contrary movements of extension will be most marked, so that we may divide them as follows:

Abasia | Paralytic
Ataxic | Trembling form
Choreiform

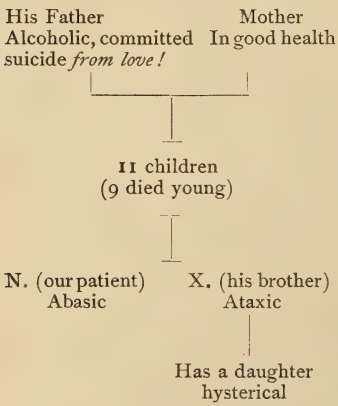
I must now detail the history of our patient. He is employed in Chaix's large printing office, and lives in a very small room. On November 15 last he desired to heat up a drink he had, and lighted an open fire to do so, and then laid down on his bed and fell asleep; when he woke up three days afterward he found himself in the Hôtel Dieu hospital. Was this loss of consciousness asphyxia-coma? I do not think so, as the latter never lasts three days—rarely over twelve or fifteen hours, when they either sleep or die. We know also that in his case on the second day, a child, who knows him, came to the hospital to see him, and the patient answered his questions without however seeming to recognize the child; and, moreover, he now does not remember this fact, so that he has amnesia, which you know often follows asphyxia from charcoal fumes.

We must ask now if all the phenomena seen in this case can be due to carbonic oxide poisoning? The nervous symptoms following such poisoning have been thoroughly studied by Bourdon, then by Leudet, Lancereau, and Rendu. They are of two classes: amnesia, of which I just spoke, and paraplegia, accompanied by anæsthesia; and trophic troubles—bullæ, scars, herpes, etc.—which get well sometimes, and are often attributed to peripheral neuritis. This paraplegia comes some twenty days afterward; during this time the patient comes out from his coma and returns to his usual occupations, although he is a little stupid; then hemiplegia comes on, which terminates quickly in death. Klebs and Gosetten at autopsies found symmetrical softening of the brain without any vascular obliteration; we do not know the pathogenisis of this trouble.

This is all the knowledge we have of this poisoning by carbonic oxide; what is wanting, and what should be shown, is hysteria. I say this with assurance, as I base my

[1] Prof. Charcot presented this patient cured at the next lecture.

remark on analogy with the other poisonings that occur from alcohol, lead, and sulphide of carbon, which all provoke neuroses. Nevertheless, if hysteria come after carbonic oxide asphyxia, it is not so important as the amnesia and other symptoms; it is an hysteria of a oxy-carbon nature. The toxic principle here is only the occasional cause that reveals the neurosis in a patient predisposed to it. The antecedent history of our patient is much in favor of my theory. He is predisposed to hysteria, and the asphyxic accident simply showed its manifestations. During his coma they applied mustard plasters to his legs, and on coming to he saw the scars. He staid at the Hôtel Dieu twelve days, and a short time afterward he found that he could not walk well; from this he became terribly frightened lest he would have serious difficulty from this infirmity; and in the mental situation he was then in, we can readily see that the phenomenon of auto-suggestion produced the actual disorder that came on then. However, he continued to walk for ten days when he struck against a person in walking, and from that moment commenced the trembling method of walking I show you. Just note the succession of events on his genealogical tree, which I placed on the black-board, which will give us an explanation of his actions:



The past of N. is also interesting. As a child he was tormented by a nightmare, which was always the same. This you are aware is a sign showing nervous origin. He constantly saw himself sleeping at the base of a high wall, on his left side; and he could see at the top of the wall the ends of a ladder, which was on the other side of the wall. On the ladder soon appeared an ugly, bloody figure of a man; the latter held an immense stone which he let fall on N, who awoke screaming. This dream came on almost every night up to the age of 14 or 15, and with such regularity that his mother watched his first sleep to wake him when he cried. His education was very good, and he read many books, among them Moliere, Lamartine and Moreau.

The patient tried the profession of locksmith, but had to give it up owing to vertigo. Some three years ago a friend of his, in whom he had placed every confidence and affection, was arrested for theft, and since then the patient's existence has been broken; he cries for nothing, even the slightest cause brings on an emotional attack, so that we can readily conclude that he is suffering from hysteria.

We conclude then that we are in the presence of a very singular case, in which walking alone is affected. Where is the seat of the mechanism here? We are led to admit two centers. We know that there is one in the brain, where the mental acts hold their seats and give orders; the other is spinal, and receives the commands, while it also represents the mechanism of execution of them. We have several reasons for believing this. It is told of the Emperor Commodus that he had ostrich's heads cut off, but they continued to walk; ducks also will flap their wings and walk a certain distance after decapitation; the same is true of serpents, which will coil themselves around a stick after losing their heads.

But does not man also walk automatically? I can cite an anatomico-pathological fact which is quite demonstrative of this. I have spoken to you before of spinal marrows, found in autopsies after Pott's disease, which were divided into two parts held together only by a few nerve fibres; and yet these patients walked. The mechanism of walking is found then in the lumbar swelling, and you may readily figure to yourselves that there exists here, in the spinal axis, as many independent centers as there are modes of progression.

As to the prognosis of this case, I have already said that he can be cured quickly. What shall be the treatment? As he is depressed and anæmic, we shall use iron with hydrotherapy. We will also teach him how to walk in a certain way. Perhaps he is hypnotizable, and we can cure him by suggestion; but I admit that, in my service at least, I have not been spoiled by success in this method of cure, as most of the cases of hysterical manifestations in males have failed to be cured by suggestion.

COMMUNICATIONS.

REMARKS ON THE USE OF THE OBSTETRIC FORCEPS.[1]

BY CHARLES P. NOBLE, M.D.,
PHILADELPHIA.

It is by no means my intention to bring before you a formal disquisition upon the obstetric forceps; but rather to confine my remarks to the impressions or opinions concerning the forceps, their use and abuse, which have been impressed upon me by my observation and experience. I am the more inclined to bring the subject before you, because the subject of forceps delivery has occupied my attention to a considerable degree of late; for within a short time seven women have been under my care in private and consultation practice, who have required the aid of the forceps to enable them to complete their labors.

Forceps applications are naturally divided into high forceps and low forceps applications; that is, at or above the brim of the pelvis, and below the brim—in the cavity or at the outlet. This division has not only an anatomical, but also a very practical basis. For, as all the initiated know, a forceps application at the outlet, the indication being simple inertia, is one of the simplest of operative procedures; while the high forceps operation is apt to be exactly the reverse, and often requires the greatest skill and judgment to bring it to a successful termination.

My own experience with high forceps applications is small, being limited to three cases, but I have observed and have assisted at a number of others. The histories of the cases requiring high forceps application are as follows:

Mrs. E. C., 22 years old, a primipara. The patient fell in labor December 11, 1888. After eighteen hours the membranes ruptured; and sometime later, no progress being made, I was asked by her attendant to see her with him. I found her a healthy Englishwoman; but she was exhausted by her labor. The vagina was hot and dry; the cervix fully dilated, but prevented from slipping over the head by lack of descent of the head. The head was in the 3d position, R. O. P., semi-flexed, and impacted. It neither advanced nor receded with the pains, and the doctor informed me that it occupied at the time I saw it the position it had originally assumed. My attention was arrested by a fleshy strip attached to the cervix, which, after it was drawn down, I found to be a strip of the cervix; and indeed, as examination some weeks after the labor showed, it was the entire anterior lip of the cervix. This strip of tissue was deeply congested, as was the vagina also. The indication was plain—the impacted head had to be brought down and the obstructed circulation relieved. The woman's general condition also demanded delivery.

The Wilson-Davis forceps were applied, twenty-three hours after labor began, and an hour was taken to complete delivery. There was so little room about the head that I thought the pelvis was rather small; but subsequent examination disproved this. The apparent lack of room was due partly to the large size of the child's head, partly to œdema of the soft parts, and partly to the absence of flexion. It was not possible to apply the forceps over the parietal eminences. One blade was applied over one frontal bos, the other over the opposite occipital bos. Very gentle traction efforts were made, due regard being paid to the already torn cervix, and to the œdematous tissues.

After the head was brought to the floor of the pelvis the forceps were removed and internal rotation assisted by manual efforts. The forceps were then reapplied and the head slowly delivered. Owing to the congestion of the tissues laceration of the perineum was anticipated, and it occurred. The child was born in the condition of asphyxia livida, but was easily resuscitated and afterward throve. There was some bruising and a slight laceration of the integument of the forehead, which healed in a few days. The torn strip of cervix was now pulled down, ligated, and removed. The perineum was sewed with much doubt as to the result; but excellent union was obtained. Full antisepsis with douching was employed. The puerperium was normal. Three weeks later I searched for the silk ligature in the cervix but did not find it. The patient was anæsthetized with chloroform.

Mrs. O., 26 years old, a primipara. The patient fell in labor January 27, 1889. She had had prodromal pains for some days. I saw her with her attendant twenty-one hours after he had been summoned. The pains at first had been distant, but later they became more frequent, and ultimately almost continuous. Her pulse was good

[1] Read before The Northern Medical Association of Philadelphia, March 8, 1889.

but she said she was very much exhausted, and was suffering severely. Palpation was unsatisfactory, owing to the rigidity of the uterus. The lower segment felt to me unusually thin. Auscultation detected the fœtal heart sounds. Touch showed that the occiput was presenting to the left iliac bone, and that the head was fixed in the brim. The cervix was half dilated and very flaccid. Incomplete dilatation was evidently due to non-descent of the head A bag of waters was present, although the attending physician told me the patient had been losing water. Through the membranes a well-marked caput succedaneum could be felt. The sacrum could easily be reached, and subsequent examination showed an indirect conjugate of four and a quarter inches. My opinion was that the patient could not deliver herself; so I ruptured the membranes. Chloroform was then ordered. About an hour elapsed from the time I saw her, until the forceps were applied; but in that time no progress was made. I applied Hodge's forceps with difficulty, and somewhat to my surprise I got them over the sides of the head. One hour was taken in extracting the head, and I was obliged to make more vigorous traction efforts than ever before. The brow slipped off the brim with a distinct shock, easily felt by the hands, and apparently with an audible sound. The child was born in the state of asphyxia pallida, the heart was pulsating about thirty times per minute. Efforts at resuscitation failed, and the heart ceased to beat twenty minutes after the birth of the child. A slight rent occurred in the perineum, started by backward pressure over the lock of the forceps. Two sutures were introduced, and partial union resulted. Full antisepsis was employed. The douche was used before and after the forceps. The puerperium was normal. The most striking feature in the case was the presence of a caput succedaneum, with a bag of waters.

Mrs. R., 30 years old. The patient had borne three children. She fell in labor February 3, 1889. Her two previous labors were lingering; one baby was still-born. I saw her in consultation with her physician about twenty-three hours after labor had begun. The brow could be made out by palpation to the right, and the fœtal dorsum to the left. The fœtal heart was plainly heard. Touch detected a cystocele; a dilated os, ready to slip over the head; and the head presenting in the first position—the occiput, however, was farther back than is usual in this position. The attending physician stated that no progress had been made for some hours. On consultation we decided that labor could be completed spontaneously only after long delay; that probably the forceps would be necessary later for inertia; and that without early delivery the baby would likely be dead, as was the preceding baby.

We recommended the use of the forceps and I proceeded to apply the Hodge forceps, under ether anæsthesia. After the patient was etherized and a more careful examination became possible, the conjugate diameter was found shortened—the sacrum being within reach. No accurate measurements were taken; the true conjugate was estimated at three and three-quarter inches. The application of the left blade was difficult, because the end of the blade impinged against the shoulder of the child. It was not possible to apply them to the sides of the child's head, so they were applied obliquely. Traction efforts easily brought down the head; but unfortunately the bladder did not ascend, and it was not possible to push it above the head between the pains. Her attendant had no better success. After forty-five minutes—the head having meantime been brought into the cavity of the pelvis—it was thought best gently to pull the head by the bladder, which was accordingly done. The child was in the state of asphyxia pallida when born, and while it soon gasped occasionally, and later had shallow respirations, more than an hour elapsed before it was in a fairly satisfactory condition. Partial antisepsis was employed, and the douche used the following day. The woman was unable to pass her water for forty-eight hours, but afterward had no trouble. The puerperium was normal.

The problem as to how to manage the cystocele was a serious one. Had the labor been normal, I should have advised the knee-chest position. But under ether anæsthesia this was manifestly impossible. The bladder could not be pushed up because the head occupied all the space between the sacrum and pubes. The perineum was slightly rubbed by backward pressure with the forceps, but a suture was deemed unnecessary.

In these cases the forceps were applied according to the prescribed rules. The head was grasped as gently as possible, sufficient pressure being made to prevent slipping. Between the traction efforts the pressure was intermitted to allow of equalization of the cerebral circulation. When the head is grasped obliquely, unusual care

is required to prevent the forceps from marking the child's head. This is especially true of the various modifications of the Davis forceps, and the Hodge forceps; it is less true of the heavier forceps with kite shaped fenestræ, such as the Simpson forceps. Traction efforts were made intermittently, as far as possible during the pains. The least traction was made that would cause the head to advance. To avoid undue traction the sitting posture was maintained, and the elbows allowed to rest on the knees, so that the traction was made principally by the forearms. By means of pressure over the lock in a downward-and-backward direction, in addition to the traction at the end of the handles, the head was drawn upon somewhat in the axis of the superior strait.

My experience with these cases is sufficient to convince me that the ordinary forceps is poorly adapted for use at the superior strait. The difference in the force which is necessary to bring the head through the superior strait as contrasted with that which will bring it through the inferior strait, is a sufficient demonstration that a very considerable part of the force employed when the ordinary forceps is used at the superior strait is wasted—worse than wasted, for it is lost in injurious pressure of the head against the soft parts covering the pubic bone. I have never employed Tarnier's forceps, but I fully accept the principles upon which that forceps is constructed; and from observation I have personal knowledge, that Tarnier's forceps will bring the head from the brim to the floor of the pelvis with far less effort on the part of the operator, than will the ordinary forceps. In the future I intend to use this instrument in high forceps applications.

I believe it best, with the head at the superior strait, to use forceps with a heavy, non-cutting blade, and with the kite-shaped fenestræ; and so to apply the forceps that the pelvic curve of the blades is approximately parallel with the curve of Carus. As already stated, I consider the axis-traction attachment of Tarnier a great advantage, as with its use less force is required to deliver in a given case, than without it.

I did not apply the forceps to the sides of the pelvis in the three cases reported, because I had with me either the modified Davis or the Hodge forceps, which, in my judgment, are not adapted to the application over the face and occiput of the child. The bevelled, sharp, almost cutting edges, of these forceps would almost certainly disfigure the face of the child; not to mention the danger of wounding the maternal soft parts with the projecting heel of the blade—especially of the Davis pattern—in which the heel is only out of harm's way when the blade is applied snugly to the side of the child's head.

The low forceps applications have been made because of inertia of the uterus. Sometimes their use has been hastened by recognizing weakness, extreme rapidity, or extreme slowness, of the fœtal heart beats. In general the forceps have been applied to the sides of the child's head. This is sometimes impossible when the occiput looks toward one ilium and the brow toward the other; no matter whether the position is primitive or the head undergoing internal rotation, the occiput having originally been posterior. Chloroform has generally been given to the "obstetrical degree."

Traction efforts have been made as nearly as possible in the axis of the birth-canal, and during the pains, when pains were present. Half an hour has usually been the time taken to deliver; the object being to secure relaxation and not rupture of the perineum. Delivery has been hastened several times when forceps were applied because of fœtal heart failure. Between the traction efforts the forceps have been allowed to lie loose in the birth-canal, compression being intermitted. The gentlest traction efforts have always succeeded; and vigorous traction has always been avoided. Great care has been taken to feel whether or not the heel of the forceps blade projects beneath the vertex, and to remedy this when it is found. Unless this is done it is extremely easy to cut the posterior wall of the vagina—especially before internal rotation has occurred. This is especially the case with the projecting heel of the modified Davis forceps. It is perhaps needless to say that such cases have come under my observation. When the occiput has crowned, the forceps usually have been removed, and the final delivery left to the patient, assisting her by manual efforts. In a few cases I have purposely left the forceps on; and a few times their removal has been difficult and they have been allowed to remain. When the forceps have remained on but little traction has been made, for as every one knows little force is required to effect the delivery of the head after the occiput has crowned.

The instruction of the books that the handles, while the head is delivering, should be very much elevated and finally lie almost parallel with the abdominal wall, has purposely not been followed. I am convinced

that one of three accidents is often produced by this practice: 1. Extension is unduly hastened and exaggerated, and consequently the perineum is apt to be ruptured. 2. The extremity of the forceps blade is apt to cut the soft parts of the pelvic floor—especially when they are not snugly applied to the head. 3. The vascular tissues of the vestibule and lower anterior vaginal wall are apt to be cut by the anterior edge of the forceps blade. This is especially prone to occur with the comparatively straight blade of the Hodge forceps. I have known this accident to happen in good hands several times.

When the head is distending the perineum the reflex contractions of the abdominal wall and of the uterus are almost always sufficient to complete delivery. Hence traction efforts at this time are rarely necessary. It is sufficient to allow *gradual* extension of the head to occur, and at the same time to keep the sub-occipital region in close apposition to the pubic arch.

In occipito-posterior positions I have usually waited patiently for anterior rotation to occur, or I have assisted rotation manually by pressing the brow upward and backward during the pains, or by applying the thumb behind the occiput and two fingers in front of the brow, and impressing a rotary motion on the head. I have been surprised to see how easily rotation can be effected sometimes. When the natural powers have been unable to complete the delivery, the forceps have been applied. In the high forceps case already detailed the head was brought to the floor of the pelvis, rotation effected, and then the forceps reapplied.

The indications for the use of the forceps are various. In general, it may be stated that the forceps are indicated, after the head has engaged in the superior strait, whenever the natural forces are unable to effect delivery with safety to mother and child. This limitation excludes a discussion of the cases in which from contraction of the pelvis, large size of the head or other cause, the head remains movable above the superior strait. On the other hand, whenever the head engages in the superior strait, especially if the biparietal diameter is below the brim, there is reason to believe that the natural powers assisted by the forceps can effect delivery.

Of course the indication varies as to whether the head is at the brim, in the cavity, or at the outlet of the pelvis. A forceps application at the brim, even in skilled hands, has certain inherent dangers, and is an operation of gravity; whereas an application in the cavity or at the outlet is exceedingly simple, and of itself, in skilful hands, can hardly be considered in any case as adding to the danger of either mother or child. Perhaps an exception may be made when the occiput is posterior or toward one ilium. Under these circumstances there is some danger of injuring the child.

Labor may last for a long time when the membranes are unruptured, and the head not impacted in the brim, without serious consequences. Under such circumstances the only indication for instrumental interference would be exhaustion on the part of the mother or cardiac failure on the part of the child. When the cause of delay, or arrest of the head at the superior strait, is a slight disproportion between the size of the child's head and the pelvic inlet, instrumental interference should not be lightly undertaken. The head becomes moulded to correspond with the pelvis, and nature can often do better than art. In such cases the membranes should be preserved. When however the symptoms of exhaustion in the mother supervene, or the circulation of the child becomes embarrassed, delay is no longer permissible. As is well recognized, in order to apply the forceps at the brim, the cervix must be dilated or dilatable, and the membranes ruptured. If these conditions do not exist they must be induced. In case the membranes rupture, the conditions are quite similar to those in which delay occurs in the second stage of labor, with the head below the brim.

It is not my purpose to consider unusual indications for the use of the forceps either at or below the brim, such as heart disease in the mother, eclampsia, threatened rupture of the uterus, etc. The usual indication for the use of forceps in the cavity or at the outlet is a lack of relation between the expulsive force and the resistance to be overcome. Time elapses and little if any progress is made. More or less complete inertia of the uterus is present. The second stage of labor is normally completed in from thirty minutes to two hours; and the time may be somewhat extended without detriment to either mother or child. Still, when the second stage of labor is prolonged beyond two hours, this fact itself should be a cause of watchfulness—the condition of the soft parts of the mother and the life of the child being especially borne in mind. Since there is no fixed limit of time for the conclusion of the second stage of labor, it is evident that the length of the second stage cannot be a positive indication for

the use of the forceps; at the same time it should ever be borne in mind that the danger to mother and child increases with the length of the labor, and especially with the length of the second stage of labor.

It is often stated that the forceps should be used whenever the head ceases to advance during the pains, or, what is the same thing, when the head ceases to recede in the intervals between the pains. This is unquestionably a sound general rule. Exhaustion on the part of the mother, which is not relieved by restoratives, is also a pressing indication for the use of forceps. A positive indication is extreme slowness or extreme rapidity of the fœtal heart beats. The fœtal heart should be listened to from time to time during every labor, and especially if the second stage is prolonged.

Finally, I think the question of the operator is a large factor in the indication for the forceps. The skilful man may apply them with relative frequency, and only good result; while the unskilful man may apply them seldom and only evil follow. In my own hands the forceps have been applied in fifteen per cent. of the cases; and yet I am an opponent of the too frequent use of the forceps. The apparent frequency is explained by the fact that most of the forceps applications were in consultation cases. Among my own private cases the forceps have been applied in seven per cent. of the cases. Probably this per cent. will increase in the future.

The dangers arising from the use of the forceps are seldom insisted on. Yet they are not the less real.

The forceps may injure both mother and child. The particular dangers differ with the peculiarities of the case. When the forceps are applied within the uterus, the head being at the superior strait, the uterus may be perforated, lacerated or contused. With proper care and gentleness it hardly seems possible to perforate or rupture the healthy uterus. The principal dangers to be apprehended are contusions of the lower segment of the uterus, and lacerations of the cervix. Contusions are to be avoided by making traction as nearly as possible in the axis of the superior strait, so that the tissues of the uterus may not be caught between the bony head and bony pelvis; and also by seeing that the edges of the forceps blades do not make injurious pressure on the tissues, more especially of the cervix. Laceration of the cervix is no doubt at times unavoidable. Laceration is to be avoided by securing full dilatation before applying the forceps, if possible; and in every case by using gentle traction efforts, and by avoiding the hasty extraction of the head through the partly dilated os.

When the forceps are applied to the head, in the cavity of the pelvis, the danger of injuring the maternal tissues is not great. It is possible, however, in case the cervix has entirely drawn up over the head so as to be beyond reach, to catch the cervix between the end of the forceps blade and the child's head, and thus perforate the cervix or even tear loose more or less of it. This is especially apt to occur when the long blade of the Davis pattern is used, and it does not seem possible to prevent the accident when these forceps are used. I have known this accident to occur to experienced obstetricians, on two if not three occasions. Also, if the forceps are not applied over the parietal eminences, the projecting edge of one blade may cut the vagina and pelvic floor, unless great care is exercised. This is of course most apt to occur with forceps having wide blades. The nature of the injuries at the outlet which may be caused by the forceps and the methods of avoiding them have been sufficiently indicated already.

The possibility of introducing septic matter into the birth-canal with the forceps necessitates more than ordinary antiseptic precautions. In this connection the dangerous character of the ancient green flannel forceps-bag deserves attention.

The child, too, may suffer. I have seen the skull of the child fractured by the projecting sacrum in a case of labor in a woman having a rachitic, flat pelvis; and yet no undue force was applied with the forceps. Had inordinate traction been used what would have been the result? Undue compression of the forceps may lead to laceration of the integument of the head; depression of the skull; compression of the brain; rupture of blood vessels and hæmatoma, either within or without the skull; death of the child, or worse, paralysis or epilepsy. Such cases are not rare. A rarer accident is the compression of the umbilical cord by the blade of the forceps. These accidents in my judgment, are most liable to occur when a forceps with long, wide, closely approximated blades are used. These not remote possibilities should ever be borne in mind, and the greatest care exercised to avoid them.

It is commonly believed, and I think rightly, that the child is least liable to injury when the forceps are applied over the

parietal eminences of its head, the blades being more or less parallel with the occipito-mental diameter; hence, except when the head is at the brim or high in the cavity, with the occiput directed toward one ilium, it is incumbent on the operator to endeavor to apply the forceps after this manner. Should it be impossible, however, the danger to the child is greatly increased. It is then necessary to apply the forceps over one frontal bos and opposite occipital bos, or directly over the brow and occiput. Under these circumstances the greatest gentleness is necessary to avoid injuring the child.

I purposely pass over a further discussion of the merits of various forceps in oblique applications when the head is in the cavity. Also I must omit mention of the use of forceps when the face or the breech presents.

I have not been able to make my remarks as systematic and concise as I wished, but I hope I have made clear the views I wished to elaborate and illustrate. It seems to me that the following are the requisites for the largest success in the use of the obstetric forceps:

1. A thorough knowledge of the anatomy of the organs concerned in parturition.

2. An intimate acquaintance with the mechanism of labor, both when it is normal and abnormal.

3. An equal knowledge of the accidents of labor, and of their prevention.

4. Knowledge of the principles upon which the forceps act; the differences between the action of the different varieties of forceps; and the advantages and disadvantages of each variety, in the varying conditions under which the use of the forceps becomes necessary.

5. The use of the least force, in compression and traction, that will complete delivery.

The object in using the forceps is not only to complete delivery, but also to complete it without injury to mother and child; or, when this is not possible, to complete it with the least injury to mother and child. It seems to me that this desirable end will be best secured when the forceps are used under the conditions named.

—Drs. J. A. Watson, S. W. Battle, F. T. Merriweather and others give notice in the *North Carolina Medical Journal*, March, 1889, that an application will be made to the Legislature of North Carolina for a charter incorporating the Western North Carolina Medical College.

GONORRHŒAL RHEUMATISM.[1]

BY CASPAR W. SHARPLES, M.D.,
RESIDENT PHYSICIAN, PHILADELPHIA HOSPITAL.

(*Concluded from p.* 510.)

Case V.—Henry H., 27 years old, an iron-worker, with no family rheumatic history. The patient is a moderate drinker. Three years ago he had his first attack of gonorrhœa without complications. In May, 1887, he had a second attack, beginning six days after connection. During the acute stage he was working and using injections, and in three weeks articular trouble appeared, the urethral discharge having completely ceased two days before. The day before the joints became affected he was more exposed than usual. The next morning he could not get up on account of a sore and swollen left ankle. The sacro-iliac articulation and left knee next became involved. For six months he was disabled with the knee and ankle trouble. Fully eight months after the gonorrhœa, the right hip was affected and has so remained ever since. The right instep has also suffered. During all this period gleet persisted, but has now ceased. The ankles off and on have been so painful that he could not walk for a week or so. The heart has never been affected. Below the malleoli there is now an œdematous infiltration. There is swelling on the outer margin of the os calcis and about the tendo Achillis; the lateral movements of the joint are much impaired, though flexion and extension remain quite good. He has had the heel pain so often observed, and has had all forms of treatment except operative. He has had iodides, salicylates, bichloride, quinia, iron, and all with no effect. The cautery was applied to the hip, and repeated, with temporary results.

Case VI.—J. K., a man 18 years old, was admitted December 6, 1888. There was no history of rheumatism in his ancestors. One brother is rheumatic. The patient does not drink and he denies a venereal history. When he was admitted he had retention of urine for three days, with a small amount of pus at the meatus, which, on examination, showed gonococci. Far back in the urethra there was found a stricture. About the end of August he had an acute trouble in the left foot, the pain appearing before the swelling. There was no redness. The toes subsequently became involved; then the

[1] Read before the Philadelphia County Medical Society, March 13, 1889.

left knee and hip, with much pain and tenderness; the shoulders and lumbar region next became affected, after which pain appeared in the right ankle and foot without manifest change in their appearance. The sacro-iliac joints were last affected. The right elbow was repeatedly affected and remained sore for a month, and now there is partial false anchylosis. For the past six weeks, the left leg has been swollen, œdematous, not tender, but painful on motion. The patient's face presents a waxy dull appearance, a subjective heaviness, and a new fulness under his eyes, especially in the naso-malar fold. The mental region is also full. The patient is anæmic; he sweats a good deal in the feet and legs, and slightly over the rest of his body. He has had no fever while in the house. The disease has made no appreciable change. The heart has not been affected; the urine shows nothing. Treatment was with counter irritation, rest, and oil of gaultheria.

Case VII.—Robert H., 31 years old, was admitted August 27, 1888. No rheumatic history exists in the family. The patient is not a drinking man, but indulges freely in venery. He has had gonorrhœa four times; the first and second time without articular mischief, but at the third attack the joints were involved and have remained so ever since. November 4, 1884, he had an acute non-specific iritis, from which he recovered. In Jan., 1885, he had gonorrhœa, and a recurrence of iritis in the right eye, and soon after this pains came on in the joints, and within ten days after the onset of the gonorrhœa they were acutely inflamed, the inflammation being accompanied by a temperature of 106°. The knees, ankles, toes of the right foot, hip and the elbows were involved, and when the articular mischief appeared, the urethral discharge stopped, and did not reappear for six weeks. He was given twelve grammes of salicylic acid daily for forty days, with great relief from pain, though it caused much gastric distress. During this attack he had scleritis, tenderness of the right eye, and iritis. He was in bed till the middle of March, when his articular pains were relieved though not completely. In April, 1885, the joints were still sore. Three times daily he had rubber bandages applied for thirty minutes, and a daily hot bath, with temporary relief. In May, 1885, he had an iridectomy performed upon the right eye with some relief. Subsequently he took warm mud baths with great benefit. In June he had iritis of the left eye, during which he received iodide of potash and pilocarpine. Throughout the summer of 1885 he continued disabled. In Sept., 1885, he again had iritis. In Dec., 1885, he was quite free from joint trouble. At this time he again contracted gonorrhœa, and in eight days he had a recurrence of iritis in the right eye. The urethral discharge continued until March, 1886, when the left shoulder was involved, accompanied by double iritis lasting for six weeks. The joints of the feet were much affected. In the winter of 1886 and 1887 he was pretty well. In March he again had iritis in the right eye. In June he again had gonorrhœa, followed by involvement of the feet, toes and ankles. Since his admission he has had persistent gleet and attacks of iritis of long duration. The plantar arch is nearly gone. He walks with great difficulty and has a peculiar heavy appearance, with an enlarged naso-malar fold. He is anæmic and pale. The heart is normal. The urine contains oxalates. Treatment has been of no benefit.

Case VIII.—G. S., a man 52 years old, was admitted October 26, 1888. He had been in the house before with the same trouble. The family history is negative. At eighteen he had chancroids and buboes. At twenty-two he had his first attack of gonorrhœa, with gleet, lasting for a year. About three weeks after he seemed to be cured of the acute affection, the ankles and knees began to swell, confining him to bed for eight weeks. Four years after that he had a second attack of arthritic trouble, the ankles and knees becoming as when he had gleet. At this time he was laid up for eight weeks. Two years subsequently after gonorrhœa the rheumatic affection recurred. In two years he had a fourth attack, in which the joints were affected. In the first and second attacks he had ophthalmia, and with each subsequent attack the eyes became injected and their secretion increased. The present is his seventh attack, and began four months ago, following urethritis on the third day. The ankles, knees, phalangeal joints of the right index finger, the metacarpal joints and wrists were affected in the order of mention. The right sterno-clavicular joint has also been involved. The joints have always been red, with a moderate degree of swelling, which was more marked in the first than in subsequent attacks. For the first time the hands have been involved. The ankles and right carpus are stiff. Each subsequent attack seems milder. There has been no heart trouble and no sweats. Treatment of the urethra and joints was local,

and sulphide of calcium was administered. The man left the house slightly relieved.

Case IX.—L. A., a colored man, 39 years old. No rheumatic family history exists. He has been much exposed to cold and wet, and especially for three years while in the army. He is not a drinking man. He has now advanced phthisis. In July, 1876, he had gonorrhœa, the discharge appearing in six days after infection. Two weeks later he had a severe wetting. The following morning he could not move. In three days the urethral discharge left, and the elbows and ankles became painful and swollen. The knees were stiff as well as the hips and shoulders. The temporo-maxillary joints were so swollen that he could not open his mouth. The left ankle was the part most affected. It was thirteen months before all the joint affection left. Up to the present he has had no further joint trouble. Early in Dec., 1888, he had pain and swelling in the left ankle, and extreme tenderness. With this again came some urethral disturbance, though he has not had gonorrhœa since the first attack. For the last attack he had iodine applied, massage employed, and salicylates administered with good effect. No murmur is found at the apex, but a distinct systolic murmur at the second left interspace.

Case X.—F. M., a woman 19 years old. The patient's mother had rheumatism. She herself has no previous venereal history, and never before had had rheumatism. She does not know the time of infection, but about nine weeks after she first saw the discharge, she had pain in the joints. The gonorrhœa was complicated by buboes. The swelling first began in the right wrist, which was only slightly red, and extended into the hand and fingers. There is now a peculiar induration and thickening of the dorsal surface of the hand. The skin is dark and over the fingers decidedly glossy. The temperature has not been above 100°. Improvement has been slow. The condition as above mentioned is at the end of the seventh week. The patient appears heavy in the face, with a large naso-malar fold, and she is anæmic and pale. The heart is normal. She has had iron and quinia and has made slow improvement.

The third class, or "acute gonorrhœal rheumatism," is much rarer than the former. The pains wander from joint to joint, and then suddenly, often at night, one joint suffers the severest pain, and soon periarticular œdema and fusiform enlargement appear, so that the affection has been described as an enlargement of the bones. The pain is worse at the plane of articulation, from which point swelling extends, usually along the dorsal surfaces of the wrist or ankle. The joint has heat, but may be pale or red, and febrile disturbance is not marked. The trouble may undergo resolution, or may go on to suppuration, but most commonly ends by fibrous anchylosis. Such a class of cases may most readily be confounded with acute rheumatism, as it runs a less chronic course and comes on more rapidly. Though I have no case recorded here under this heading, yet I think that Case I properly belongs here; it was put with the others on account of the cardiac condition.

The fourth class, "chronic hydrarthrosis," may occur in connection with the polyarticular variety, or may be monarticular alone. It usually attacks the knee, and a few cases are recorded in which it attacked both knees at once. The effusion comes rapidly and insidiously into the joint, without any heat, change of color, tenderness, marked pain or fever. Pus formation following it, is rare. It is curious to note that in many books we find only this form described, and no mention made of other varieties of gonorrhœal rheumatism. From the case, which I have added as an example of this, an attempt was made to obtain cultures from the serum withdrawn from the joint, but with no success.

Case XI.—T. B., a man 23 years old, was admitted January 15, 1889. The patient is a temperate man. Fourteen months ago he had his first attack of gonorrhœa, during which he let a tub fall upon his foot, which became sore and swollen. Three weeks before his present admission, he again became affected with gonorrhœa. The discharge from the urethra became watery and thin. The right knee was swollen ten days after the discharge appeared. The swelling progressed rapidly, and within two days he could not get out of bed. He did not have much pain, but had a good deal of swelling. On admission there was marked distension and fluctuation in the affected joint. Cold bichloride towels were applied over it with apparent benefit and rapid disappearance of the effusion. On the 22d, the left wrist was swollen and the arm stiff and painful. On the 24th, the ankle became swollen, without pain. The urethral discharge has been slight and is now most abundant. Salicylate of soda internally and bichloride applications locally were ordered. The man is now better, with slight swelling and stiffness of the knee.

Dr. Osler has furnished me with notes of a case of "multiple arthritis" of gonorrhœal origin. A. B., 31 years old. In 1869 the patient had an attack of gonorrhœa, which was followed by inflammation for ten weeks. In 1876 he had a second attack, accompanied with swelling of both feet. The other joints gradually became affected and he had a prolonged illness, the attacks recurring alternately with periods of comparative comfort. He was incapacitated and had more or less joint trouble for eight years and eight months. He went about to various hot springs and sanitaria, at which he secured only temporary benefit. Dec., 1887, he had three attacks of gonorrhœal rheumatism, after nearly three years of fair health. Within a month of that time he was attacked in the ankles, knees, and hips. Jan. 12, 1888, it was noted that he had had pains with slight swelling in the metatarsal and phalangeal joints, and also in the right ankle, knees, hips, and shoulders. He was anæmic, thin and delicate looking, with slight fever and no heart affection. The ankles and toes were red and painful. At first he received gaultheria with benefit, but later Fowler's solution was substituted. He remained in the hospital but a few weeks and then went to the Hot Springs of Arkansas. This case, with some of the others, illustrates the extreme chronicity of this disease.

The fifth and last form needs no attention. It involves especially the sheaths of the tendons, the bursæ and, it is said, the periosteum. It often comes without any accompanying joint affection. There is great pain, tenderness and local swelling. The pain is more marked at night. Gonorrhœal bursitis is rare and for the most part occurs over the patella and around the olecranon. To this is due the peculiar pain, the small bursa beneath the os calcis being the one affected. Most of the above cases illustrate this class.

There is no constancy at all as regards the urethral discharge, and this does not need better proof than the fact that one author describes one period, and another another period, for the occurrence of rheumatic symptoms. Some say that the discharge stops with the appearance of gonorrhœal rheumatism, and others that it suffers no abatement. In some cases the discharge has stopped before the rheumatism appeared, and in others it persisted throughout, or to nearly the end of the attack. If the discharge stops before the attack, it may and usually does stop suddenly; and patients are apt to say that it stopped as the result of injections; or when the attack appears the discharge may suddenly be sensibly diminished and resemble gleet. The occurrence of an orchitis and an increase of the discharge, as took place in Case IV, I think quite anomalous. Otherwise the discharge presents no interest, unless it be for the purpose of diagnosis by staining it to discover gonococci. Many cases of rheumatism could be placed in this category if the genitals were carefully examined.

The theories as to the origin of this trouble are many, and are all alike in the fact that they cannot be proved. In former times it was said that the origin was by metastasis, and irritants were applied to increase the urethral discharge. There is a "reflex" theory, the physiology of which is simple. The irritation goes up through the sacral plexus into the spinal cord and to the trophic centers, and then we see the changes mentioned. Why any urethral irritant may not cause this is hard to explain, unless it be the fact that the specific element of gonorrhœa is more irritating. In some cases sciatica has been noted, due probably to the same cause.

At present the septic theory has the most supporters. In cases of septicæmia arising from gonorrhœa the prostatic plexus and urethra have been found full of pus. One line of treatment has been based on the septic view. The rheumatism is a general affection and the gonorrhœa a local one, and is so universally regarded; but in the light of the reported cases of endocarditis with gonorrhœa there may be something more in it. What the change is that occurs to make gonorrhœa a gonorrhœal rheumatism, I do not think we can yet say. In Van Buren and Keyes's article I find this statement, practically expressing nothing, but at the same time about all that we know: "It is then, an idiosyncrasy which causes a patient with gonorrhœa to develop rheumatism, and not any tendency to suffer with the latter complaint."

All measures of treatment have only little curative effect. If the urine should be too acid, use alkalies. Pain requires the application of leeches, the use of morphia and salicylates. Salicylates have the same effects as in ordinary rheumatism, viz.: to allay the pain and lower the temperature, but not to cure the affection; and they should be stopped when this end has been attained. Splints should be applied and the joints protected. Plaster has been applied even in the acute stage, with the result of relieving the pain and diminishing the swelling,

but not hastening the cure. Small doses of mercury have been recommended, along with quinine and iron. The joints should be enveloped in cotton. The urethra should be treated. In later stages apply mercurial ointment, massage, pressure, and use passive motion. In the acuter stages perhaps the application of cold bichloride cloths may be deserving of more trial.

TRISMUS FOLLOWING DOG-BITE OF THE FINGER. RECOVERY AFTER AMPUTATION.

BY CHARLES B. PENROSE, PH.D., M.D.,
PHILADELPHIA.
OUT-PATIENT SURGEON TO THE PENNSYLVANIA HOSPITAL.

The following case occurred in the writer's service at the Pennsylvania Hospital.

J. M., a woman 40 years old, was bitten by a dog on the little finger of the right hand, in August 1888. The patient received on the palmar aspect of the finger a lacerated wound, two inches in length, which divided the tissues down to the periosteum. From the beginning she suffered intense pain, shooting from the finger along the arm, shoulder and neck to the right ear. This was followed in a few days by continual tinnitus and subsequent complete deafness in the right ear. The finger was never swollen or inflamed; the wound, however, showed no tendency to heal.

Six days after the injury the patient began to experience difficulty in swallowing and in opening her mouth; and she came under the charge of the writer on the seventh day after the injury. At this time the skin of the injured finger was dry, with several blebs on the palmar surface. The wound was unclosed, presented a gangrenous appearance, with no evidence of granulation. There was no swelling of the hand or of the finger. There was continual spasm of the muscles of mastication, which prevented her from opening the mouth except to a very slight extent. There was complete deafness in the right ear, and she complained of tinnitus in the left ear similar to that which had preceded the deafness in the right.

The wound was thoroughly washed, and frequently changed wet dressings of bichloride of mercury (1-2000) were applied; and large doses of bromide of potash were administered internally. This treatment was continued for ten days, with no marked effect either on the muscular spasm, the pain, deafness or tinnitus aurium.

The finger was consequently amputated at the metacarpo-phalangeal articulation. The next day the shooting pain and the trismus had disappeared. The amputation wound healed by first intention. The deafness and tinnitus aurium continued, and were still present two months after the amputation, though the general condition was in all other respects good.

SOCIETY REPORTS.

NORTHERN MEDICAL ASSOCIATION.

Stated Meetings, March 15 and 29, 1889.

The President, DR. JOSEPH S. GIBB, in the Chair.

DR. CHARLES P. NOBLE read a paper entitled

Remarks on the Use of the Obstetric Forceps.[1]

DR. HENRY LEAMAN, in opening the discussion, said: I am glad to have a subject of such practical importance brought before the Society. The essayist has covered the subject very well, and in most points I agree with him, especially in his summary of conclusions. I have gone over the last 950 labors occurring in my practice, of which I have notes, and find that the forceps have been used 137 times, about once in seven labors. The presentation in 91 of these cases was vertex to the front (left or right). In 40 it was posterior (right or left). The forceps were applied once with a presentation of the face, where the head had been impacted under the use of ergot (given by a midwife) for three hours; once, in an induced labor; once, during convulsions; and once to the after-coming head.

I have applied the forceps 10 times at the superior strait, the indication being a shortened conjugate diameter or obliquity of the pelvis. In the remaining cases they were applied when the head had more or less completely engaged in the pelvic cavity. The use of the low forceps was rendered necessary by weak abdominal muscles in two cases of obesity; once by mitral disease of the heart; but the usual indication was delay in the second stage of labor. This delay is invariably due to a want of sufficient flexion, owing to a lack of easy adjustment between the head and pelvic canal. The head is most frequently at fault either in size, irregularity of shape, or undue closure of the fontanelles. A resisting per-

[1] See REPORTER, p. 535.

ineum will occasionally call for the use of the forceps.

In all cases the os was either dilated or dilatable when the instruments were applied, except in the case of convulsions, when they were applied as soon as the os was dilated sufficiently to admit them.

The only injury done to the mother was a rupture of the fourchette in four cases, and of the perineum in four cases—making injury to the perineum once in sixteen labors. I have never seen any injury to the child except slight marking.

The instruments used were a long-handled forceps, known as Wallace's, and a short-handled forceps known as Davis's. These I have found sufficient for all purposes.

Dr. H. W. Rihl said: How should the forceps be used? When we consider that the death of the child very often results from prolonged labor, if severe, it becomes a grave question as to how long we shall wait before interfering. My own experience has been that by far fewer children are born dead when instruments are used early. If the head has engaged for even one or two hours, the pains being frequent and severe without causing the head to advance, and if the position of the head can be accurately diagnosticated so that the forceps can be applied to the sides of the child's head, and if the os is well dilated or dilatable—I generally advise the application of the forceps. If the position is transverse, *i.e.*, if one ear is behind the symphysis pubis, I apply the blades to the sides of the head and rotate so as to bring the vertex under the symphysis. I would long hesitate before applying the forceps over the forehead and back of the head.

But the forceps are not only, as Dr. Meigs used to call them, "the child's instrument," they are also the mother's. Are we justified in allowing her to suffer hour after hour when we can easily and safely terminate her sufferings—under the plea that labor is a physiological process with which we must not meddle?

I use forceps also when convulsions occur or are impending, when labor is complicated by feebleness or disease of the heart, and when the mother is exhausted by the labor.

Many object to the forceps because the perineum is often lacerated when they are used. Do we give sufficient weight to the fact that the cases in which forceps are used are generally those in which the head is abnormally large? Would not the tear therefore be quite as likely to occur without them? Recently in a primiparous labor, after bringing down the head to the perineum, I removed the forceps, and made a careful examination of the perineum and found it intact. After the completion of the labor I found a laceration extending to the sphincter ani. Had the forceps not been removed, they would probably have been blamed for the tear.

The injuries which the forceps are supposed to entail upon the child are doubtful. Are epilepsy, idiocy, etc., due to the pressure of the forceps, or are they not rather the result of the prolonged pressure in the pelvis, before the forceps are applied? and would not an earlier use of the forceps prevent many of these unfortunate results of difficult labor?

Finally, I may remark that my opinions with reference to the forceps are drawn from an experience of more than 300 applications, in nearly 3000 obstetric cases. I almost always use the Bethel forceps, which I have had made with blades of about double the usual thickness. These thick blades are not so apt to mark the child as thinner blades. Of late years when the position of the child could not be determined with accuracy or when it was transverse, I have at times used Simpson's forceps.

Dr. D. Longaker: If Dr. Noble's paper has been carefully followed you will have noticed, whenever injuries to mother or child have been mentioned, that he has stated that these injuries are most apt to happen when forceps are used having long, closely approximated blades, with wide fenestræ and projecting heels. My own experience and observation teach me that this is true. When I began practice I used the Hodge forceps. I gave these up, partly because of the dissatisfaction I felt with their action, but largely owing to the teaching of the late Dr. Albert H. Smith, my teacher, who was a strong advocate of the modified Davis instrument, which bears his name. Upon adopting this instrument I soon began to have accidents occurring in my hands. I pinched a hole in the anterior lip of the cervix by catching it between the end of the forceps blade and the side of the head. I have also known this accident to happen to others using this or a similar instrument. A moment's thought will show that this accident is unavoidable, when as in my case the head is in the pelvic cavity and the cervix retracted beyond reach. It is of course most likely to happen with a forceps such as this, the blades being long with the ends closely approximated and thin. I also found it extremely difficult to prevent scor-

ing the vagina with the heel of the instrument. Nor did the child entirely escape. It was not uncommon to mark the scalp, especially when the forceps could not be applied over the parietal eminences. In one case in an oblique application one blade pinched the umbilical cord which was around the neck, and the other injured an eye. The child was born asphyxiated and subsequently died. With this experience I adopted the Simpson forceps, which I have used with the greatest satisfaction. Moreover, the modified Davis forceps is a powerful compresser, an action of the forceps which is least desirable to employ, as it can do only harm.

With reference to forceps for use at the superior strait, it seems to me that the verdict of obstetricians is in favor of Tarnier's instrument, especially when the indication is contraction of the pelvis. My own experience with the instrument has been most gratifying.

Dr. Leaman: It by no means follows that all who use the modified Davis forceps, which is capable of producing marked compression of the head, bring into play this action of the forceps. I condemn undue compression with the forceps as strongly as any one. It is not my purpose to detail my method of employing the forceps this evening, as I am now engaged in writing a paper on the action of the forceps, but suffice it to say that I use them very differently than I was taught by the late Prof. Wallace.

Dr. Horn exhibited a pair of Bethel forceps, which was owned by Dr. Bethel himself. The forceps had long narrow blades with a very marked pelvic curve. The blades were thin and springy, and were quite beveled. He said: I would not use this forceps owing to the exaggerated beveling of the blades. This would cause marking of the child's head, unless caught squarely. Such a forceps should only be applied to the head of a dead child.

Dr. Rihl: I have used the Bethel forceps about 300 times on living children. I object, however, to the thin blades of the pair exhibited.

Dr. G. W. Vogler: I have a pair of Bethel's forceps which I occasionally use. When other forceps slip, Bethel's often will not slip. I think it is especially adapted for use within the uterus to make the head engage. When this has been accomplished this forceps should be removed and some other substituted, as owing to the great pelvic curve, the ends of the blades are apt to injure the anterior lip of the cervix. I quite agree with those who advocate a moderately thick blade to the forceps. I think the forceps does not often cause injury, in good hands. I have not seen grave injury to the soft parts. I usually apply the forceps when the head has been stationary for one or two hours.

Dr. James Collins: But little has been said concerning the use of high forceps in the discussion. My rule is to apply high forceps when I think there is little prospect of being able to apply low forceps. I have seen the vagina scored and the perineum ruptured by the projecting heel of Wallace's forceps, as mentioned by the writer of the paper.

Dr. Strittmatter: I agree in the main with the points which have been brought out in the paper and the discussion. I wish to emphasize that I am an advocate of the frequent use of forceps. I see no objection to applying the forceps in any case when the soft parts are relaxed. Palpation and auscultation are of great assistance in forming a diagnosis of the position of the head, especially when it is at the superior strait. I have seen some injured heads due to forceps delivery, but in these there was no subsequent idiocy or deformity.

With reference to axis-traction forceps, I do not think it is possible to draw exactly in the axis of the pelvis with any forceps. The chief merit of Tarnier's forceps is, that it interferes but little with the normal movements of the head—flexion, and internal rotation—during labor.

Dr. Robert J. Hess: I have had a large experience among the insane, and considerable experience as an obstetrician, and have not been able to convince myself that the forceps are the cause of many cases of idiocy, epilepsy, or paralysis. I consider the forceps one of the most beneficent of instruments, and think that they can be used often with advantage. The only injury I have seen has been to the perineum.

Dr. Noble: Dr. Leaman has found the Wallace and Davis forceps sufficient for all cases. It has not been my purpose to discuss particularly the many forceps in use. As I indicated in my paper, however, I do not believe that there is a "best" forceps. I still believe that we should use axis-traction forceps at the superior strait—either Tarnier or Poullet's. I have found the Hodge forceps a satisfactory instrument when applied to the sides of the child's head in the cavity or at the outlet. But it is not satisfactory when applied obliquely to the head or directly over the brow and face. Hence I am inclined to think that the best combina-

tion for the obstetrician to possess is a pair of Tarnier's and a pair of Simpson's forceps. With reference to applying the forceps for the sole object of relieving the mother's sufferings, as advocated by Dr. Rihl, I have not found this necessary. Chloral hydrate and morphia in the first and chloroform in the second stage, given when labor was unusually painful, have yielded good results.

Reports of Clinics.

HARLEM HOSPITAL.

SURGICAL CLINIC—DR. MANLEY.

Local Tuberculosis.

The first two patients presented by Dr. Manley at his clinic on April 8, 1889, were typical cases of what is at the present time described by pathologists as suppuration due to tubercular trouble, and what was formerly known as scrofula or struma. Indiscriminately classifying every kind of disease of bone or gland tissue as tubercular must lead to mischief, by tending to prevent what is rational and proper in such cases, namely, the removal by operative means of the source of ulceration.

This, however, is opening the way for the removal of an endless number of joints by resection, and to other needless mutilations, in order to eradicate the tubercle, under the false assumption that tubercle is always destructive when left alone. Dr. Manley observed that while the pathological or bacteriological elements found in the joints or gland tissues of a child are identical with those of pulmonary tubercle in the adult, still there exists—and this should be always borne in mind—a vast difference in the clinical peculiarities of each. In the one case, that of children, the disease is, as a rule, curable, and generally leaves the individual with no impaired vitality. It may leave an anchylosed joint, but it does not in any way interfere with the general health. Besides, repair is the rule in scrofula or early tubercular processes, not only of areolar tissue alone, but also of bone. On the other hand, with pulmonary tuberculosis in adults, death is the rule; recovery is seldom seen, and when it does occur, the cavities show none of the originally destroyed tissue reformed, but the void is filled with a shiny cicatricial tissue.

In the case of the first patient, no history of traumatism was elicited. The child, three years old, complained of pain in the back, and weakness, which was diagnosticated as lumbar disease and treated by the plaster jacket. This having been worn three months, the pain disappeared, and the spinal lesion appeared to be arrested. A month later the mother noticed that the child could walk on the right limb only with difficulty, and that it complained of much pain at night. It was now evident, upon examination, that ulceration had commenced in or about the hip-joint, for a large accumulation of matter had formed over the great trochanter and was pressing toward the surface. This was opened, irrigated and drained, the part buried in moist antiseptic gauze, and the limb placed in an immovable dressing. No effort was made to search for the seat of bone disease, as it was decided to await results. It is well known that a small exfoliation of necrosed bone will work its own way out; besides, later, when the child has improved in strength, should a fistulous opening refusing to heal remain, the parts can be laid open and the sequestrum removed.

The second case, that of a boy nine years old, was one which was dependent largely on the same diathesis, but differed in not having originated or been hurried into action by an injury. Dr. Manley observed that while it was yet a disputed question in tubercular lesions in children, and especially those of bone, whether or not they were dependent upon injury or constitutional disturbance alone, he was decidedly of the opinion that a very large proportion was directly dependent on injury as an immediate cause. This boy injured his right forearm on its radial side by a fall some two months ago. It had been swollen and painful ever since, and was now evidently the seat of suppuration. A long incision was made, and the lower two-thirds of the radius found saturated in pus, but with a well-formed sheath of periosteal formation enclosing it. A large sequestrum of bone was then removed and the wound dressed with idoform gauze.

Knock-Knee.

The third case was one of knock-knee, due to a bowing outward of the femora. The lecturer was persuaded, from what he had seen of congenital and acquired deformities in the bones of children, that they were as often the result of weak ligaments and want of harmony in muscular action as of deficient inorganic matter. The modern method of treating these cases—which he

thought decidedly unsurgical—was to break or to cut the bones—osteoclasis or osteotomy; but while these means readily remove the deformity, they do not remedy the defect. That they certainly remove the *visible* deformity—which both the patient and the parents are most anxious about—there can be no doubt; but it is a question if, as regards the strength and general usefulness of the limb, this practice does not leave more or less displacement of bone and consequently a defect in strength. In this instance a double osteotomy was performed, the parents refusing to allow the child to remain in the hospital a year.

Traumatic Gangrene of the Little Finger.

The fourth case was one of traumatic gangrene of the little finger, extending to the metacarpal bones. This case, according to Dr. Manley, was of more than ordinary interest for two reasons, first as to the cause and second as to the treatment. The patient gives the following particulars as to the origin of his complaint: two weeks ago he scratched the back part of the little finger of his left hand in handling some boards; he dressed the finger with adhesive plaster. A few days later the wound began to fester and commenced to give him great pain; the finger and hand then swelled to a great size. Here was mortification, or gangrene, of the hand coming from a mere scratch, a really typical case of wound infection with the germs of putrid wounds. Dr. Manley remarked that it was well to notice that wounds are usually more prone to take on erysipelatous action in the months of March and April. As regards the treatment, the part, he said, should be immediately opened when pus was suspected, and the wound treated on the most antiseptic principles. In this case he would cut down and remove all tainted tissue. This, he remarked, being a case of spreading gangrene, it could be arrested only by the prompt and free use of the knife.

The gangrenous process was found to extend into the metacarpo-phalangeal articulation, whereupon the little finger and the distal end of the fifth metacarpal bone were removed, the flaps loosely brought together, and the wound well drained.

—The child of Mr. C. J. Moore, a surgeon of West Middlesex, England, was attacked with diphtheria, and the father performed tracheotomy and sucked the tube clear. Both father and child died.

PERISCOPE.

Pathology of Chronic Alcoholism.

The Pathological Society of London has devoted much time recently to a consideration of the pathology of chronic alcoholism. The discussions have been prolonged and very interesting. The following brief review of them, taken from the *Quarterly Jour. of Inebriety*, April, 1889, will prove of interest to the readers of the REPORTER:

Dr. Payne, in his opening and closing of the debate, insisted clearly on stating his belief that the ordinary pathological conception of cirrhosis needs reconsideration. He demurred to regarding it as a mere inflammation of the interstitial stroma of the liver set up by alcohol introduced through the portal vein, and producing great quantities of new fibrous tissue, which by pressure destroys the hepatic cells. He insisted that the destruction of cells and the hyperplastic inflammation of connective tissue take place concurrently, and in this view he was supported by Dr. Lionel Beale, who held that the essence of cirrhosis is atrophy of cells, and not inflammation of connective tissue. Dr. Dickinson stoutly maintained that the overgrowth of fibrous tissue is the essence of cirrhosis; and Dr. Sharkey showed specimens of apparently healthy liver cells side by side with masses of newly-formed connective tissue even in advanced cases of cirrhosis. He suggests that the liver cells seen in such connection with newly-formed fibrous tissue may be newly-formed cells; his hopeful view of the formation of new cells and new bile ducts is especially noteworthy; in other words, there may be a restoration of tissue in a diseased liver, a possibility supported, as he says, by clinical experience of cases of recovery from grave degrees of hepatic disease.

Not the least interesting part of the debate was that having reference to alcoholic paralysis and other forms of nervous disease produced by alcohol. What is eminently worthy of the attention of practitioners in this connection is the frequency of tuberculous disease in cases of alcoholic paralysis. In fact, the association of chronic alcoholism in all forms, and tuberculosis, was brought out by almost every speaker, including Dr. Payne, who said truly that the inaccurate impression that habits of alcoholic excess are in any way antagonistic to tubercular diseases must be regarded as swept away. Dr. Dickinson's investigations into the comparatively much greater frequency

of tuberculosis in publicans and others whose occupations and habits expose them to the evil of chronic alcoholism were the first to open the eyes of the profession to the fallacy that alcohol antagonizes tubercle. Many eminent medical men have felt with Dr. Dickinson that, as alcohol does so much harm, it surely must do some good. But, so far, the good that it does or the evil that it prevents has not been made very manifest. They need more definition. Dr. Izambard Owen says the statistics of the Collective Investigation Committee show that the consumption of alcoholic liquors appears to check malignant disease. This statement should now be tested very rigidly. Malignant disease is said to be on the increase. We have seen the demolition of the belief that alcohol is a preventive of tubercle; it would be some set-off against the mischief it works if it could be shown seriously to antagonize cancer.

The views and opinions of the many leading men who participated in this discussion were expressed in a scientific spirit, not as absolute or final, but as the most probable facts sustained by our present knowledge of the subject.

Relation Between Chlorosis and Menstruation.

At the meeting of the Obstetrical Society of London, March 6, Dr. W. Stephenson, Professor of Midwifery, University of Aberdeen, read a paper on the relation between chlorosis and menstruation; an analysis of 232 cases. The author observed that in the rapid progress of uterine specialism, chlorosis in its relation to menstruation had been too much neglected by the gynecologist. The 232 cases were divided into two groups: (1) where the illness was primary and occurred before the twenty-third year, comprising 183 cases; (2) where the attacks were of the nature of relapses after a period of good health (49 cases). Dr. Stephenson regards chlorosis as due to a constitutional state; but the diathesis is not necessarily associated with an impairment of the development of the body, and is not, to any marked degree, connected with defective health previous to the onset of the disease. The influence of the chlorotic constitution on menstruation before chlorosis sets in was first discussed. Tables were given to show that the tendency of the chlorotic diathesis is to accelerate the age at which menstruation first appears, and that chlorosis by itself is not a cause of retarded appearance of the catamenia. At the same time, in one-half of the cases, the functional activity is defective, and is chiefly characterized by lengthening and irregularity of the intervals and scantiness in the amount of the flow. The author's statistics were against the opinion that there is a menorrhagic form of chlorosis. In 96.6 per cent. the effect was to diminish the activity of the function, the remaining fraction being complicated with ovarian irritation. In 58.7 per cent. menstruation became scanty and irregular, and in many cases painful, while in 37.8 per cent. there was amenorrhœa for various periods. A table was given to show that there are two marked chlorotic periods: the one, of primary attacks, from the age of fourteen to twenty-one; the other, of secondary attacks, from twenty-four to thirty-one. The number of cases of the disease presents a regular curve, beginning at the age of fourteen and rising steadily to a maximum between eighteen and nineteen, then rapidly falling, to disappear altogether at twenty-two. The tendency to secondary attacks manifests itself first at the age of twenty-four, rises to a maximum between twenty-six and twenty-eight, again to disappear at thirty-two. That there may be a third period is probable, as two cases were recorded at the ages of thirty-nine and forty-one. This law applies to attacks of the disease with distinct intervals of good health between, as distinguished from the simple relapses, after periods of imperfect convalescence, frequently met with after a primary attack. The curve of menstrual age, compared with the curve of the onset of chlorosis, does not bear out the opinion that "foremost in etiological importance is the period of the first appearance of the catamenia." The fact of a periodicity in the attacks is also against it. The cause of this periodicity was considered, and the general conclusion arrived at is that imperfect evolution of menstruation, as evidenced by scantiness of the flow and irregularity of the periods, is as regular a feature of chlorosis as the imperfect evolution of the red corpuscles of the blood. These constants are independent one of the other, though a close relationship exists between them whereby the reproduction and development of the red corpuscles of the blood are governed by, or form part of, the menstrual cycle; while both are influenced by a greater rhythmic action which determines the time and activity of development, growth, and reproduction.—*Lancet*, March 23, 1889.

Treatment of Chronic Cystitis in Women.

Dr. W. Symington Brown read a paper on chronic cystitis in women before the Gynecological Society of Boston, Dec. 13, 1888, in which he reported the case of a Mrs. B., whom he visited on Christmas-day, 1887. The patient is a married woman, 63 years of age, with a grown-up family, and had always enjoyed health until 1884, when she began to suffer pain in the bladder, accompanied with frequent calls to urinate, night and day. During the whole three years she has never been able to retain her urine for more than an hour at a time, and sometimes she has been obliged to use the urinal every half hour or so. Mrs. B. had been under the care of several physicians, regular and irregular. Although naturally of a placid, happy disposition, her face showed marks of suffering and anxiety. Her pulse was 85; the temperature 99.5°. Her urine, drawn with a soft catheter, contained pus, mucus, and crystals of the triple phosphates. There was no uterine or ovarian disease. A small caruncle, growing at the lower edge of the meatus urinarius, was removed by means of a wire snare. A similar but smaller growth was found at the neck of the bladder, and this was also removed. For a period of six weeks, she took a tablespoonful of the following solution every four hours during the day; and also used it as an injection into the bladder every night and morning:

℞ Benzoic acid, pure, ... ℥ ij
Biborate of soda . . . . . ℥ iv
Distilled water . . . . . f ℥ vj
Mix.

She took lithia water as a drink for several weeks, with apparent benefit. All kinds of fermented liquors were absolutely forbidden. Her diet was carefully regulated. Salt meat, salt fish, pork, lobster, beans, highly spiced soups, fried food, and pastry were prohibited. The usual directions to overcome constipation were given. Attention was paid to position in bed, by raising the pelvis with graded cushions, so as to avoid contact of the urine with the *trigonum vesicæ*, the most sensitive spot in the bladder. At the end of six weeks the urine was free from pus and triple phosphates, and it could be retained about two hours. Early in May, 1888, she considered herself cured. As the bladder had become much contracted, Dr. Brown made an attempt, toward the close of the treatment, to dilate it by means of tepid salt water from a fountain syringe. Dilatation should be effected, he says, very gradually; for there is some risk of paralysis from overdistention; and it seems possible, when the ureters are abnormally dilated, that the kidneys themselves may be injured. Reference was then made to the efficacy of hygienic, comfortable surroundings, admirable nursing and a contented coöperation on the part of the patient.—*Journal of the Amer. Med. Association*, March 16, 1889.

Unique Presentation of a Fœtus.

At the meeting of the Philadelphia County Medical Society April 10, 889, Dr. E. P. Bernardy described a case in which a fœtus had presented in a peculiar manner. The patient who gave birth to the child was a primipara, eighteen years old. Dr. Bernardy saw her for the first time at 8 o'clock on April 8, 1889; the membranes had been ruptured four hours, the fœtus was presenting in the right oblique diameter; the presenting part seemed to be the breech, the right side deeper in the pelvic cavity than the left; the fingers could be hooked in what appeared the groin, but did not have the full feeling one would expect in a breech presentation; a sort of sulcus or fissure was in the centre of the presenting part. Passing the fingers further upward, the bone of the skull was detected. Dr. Bernardy thought that he had to deal with a double pregnancy, the breech of one presenting and the head of the other imbedded in the chest of the first. External palpation showed the uterus divided in two by a deep dent in its fundus, a large body occupying the upper left portion, and a body occupying the lower portion of the right side. He did not introduce his hand into the vagina, for the maternal parts were rigid, and had not undergone any softening, and such examination would, he thinks, have undoubtedly caused a rupture of the perineum; the os was spasmodically contracted around the presenting part. The patient not having much pain, he left her for about two hours. On his return, the entire presenting portion was grasped by the vulva, and the child was delivered in this position. It was then found that both shoulders presented fair and square, the neck, somewhat stretched, thrown forward on the chest, and the head slightly twisted sideways, lying in a cavity in the chest; the arms laid on the top of the chest, right and left side, the head between. There was hardly any pain connected with the confinement.

Dr. Bernardy said he could not recall an instance of a similar presentation.

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Physician's Daily Pocket Record, - - 1.00
Reporter and Pocket Record, - - - - 6.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

WEIL'S DISEASE, OR INFECTIOUS JAUNDICE.

The tendency of modern pathological investigation has been toward reducing the number of separate diseases through a better understanding of the underlying processes at work in their production. As the result of this tendency, dropsy and jaundice, at one time regarded as diseases, are now universally looked upon as symptoms merely; and it is only a question of time when the whole group of symptomatic diseases will cease to exist except as symptoms. While this elimination is steadily going on, it is manifest that any new applicant to the rank of a disease will be very closely scrutinized, and will have to show very good grounds for the request. This is especially true when the disease bears a man's name—a kind of nomenclature always to be deprecated and discouraged.

Within the last few years a number of papers have appeared in Germany on "Weil's Disease," an abstract of one of the most important of these papers being published in the REPORTER, May 5, 1888. Weil described the affection as an acute infectious disease associated with swelling of the spleen, with jaundice and nephritis. All four of the patients originally studied by him were vigorous young men, who were taken sick, without special prodromes, with headache, dizziness, and fever, which in one case was introduced by a pronounced chill. In the first few days after the patients were admitted into the hospital the symptoms especially noteworthy were abnormal weakness and very marked cerebral symptoms—restless sleep, disposition to delirium, somnolence; in addition there was moderate jaundice of the skin and conjunctivæ, painful swelling of the liver and spleen, and albuminuria. Digestive disturbances were present and were manifested by coated tongue, loss of appetite, diarrhœa or constipation. These symptoms persisted unchanged, or they increased in intensity, for some days, and then abated rather quickly, so that from the fifth to the eighth day a change for the better occurred; and with subsidence of the jaundice and of the swelling of the liver and spleen, and lessening of the albuminuria, the temperature slowly and gradually fell to normal. But the disease was not over yet. After an afebrile period lasting from one to seven days the fever again rose in three cases, but ceased finally in five or six days. A striking feature of the affection was the protracted convalescence, due to great weakness resulting from very much lowered nutrition. This condition was so marked that the patients had to be kept in the hospital from four to ten weeks, before they could be dismissed cured.

Looking at the symptoms of the affection more in detail, we see that the whole dura-

tion of the first attack was from six to ten days. The highest temperature during this time was attained by a rapid rise, and reached 104°, or even 105° Fahr. Defervescence was by lysis, and was completed in four or five days. In the relapse the fever did not rise so high, being on an average a degree lower than in the first attack. The pulse was moderately increased in frequency, rising to one hundred and four or one hundred and twelve. The jaundice present was not of a high grade, but was distinctly noticeable. The urine contained not only bile, but also bile acids. The stools in three cases corresponded with the moderate jaundice, while in a fourth they were clay-colored. Diarrhœa existed in three cases, and constipation in one. The urine was cloudy except in one case, and contained albumin, epithelial casts, red and white blood corpuscles—in a word, such products as are present in so-called infectious nephritis. One patient developed on the seventh day a marked roseola; another patient about the same time had red spots on the throat and face. During convalescence one patient was affected with irido-cyclitis. There was early and painful enlargement of the liver.

The diagnosis of an affection presenting such complex symptoms is unquestionably one of great difficulty. Weil regarded it as an infectious disease whose virus caused swelling of the abdominal organs, the point of entrance of the poison being probably the intestinal tract. Since his first paper, several observers have reported additional cases, and all have in the main accepted Weil's opinion. More recently, however, Professor A. Fraenkel has given a very careful study to the whole subject, and he communicates his results in a paper published in the *Deutsche med. Wochenschrift*, February 28, 1889. He rejects the opinion that "Weil's Disease" is an abortive form of acute atrophy of the liver; for the simultaneous involvement of the spleen, liver and kidneys, as well as the course of the fever, show that the process is a general infection, or—what is more probable—that it is an intoxication. It is not a disease of the nature of recurrent fever or typhoid fever, although it resembles a special form of the former described by Griesinger; but Weil was unable to find in the blood of his patients the spirilla described by certain Russian physicians as occurring in relapsing fever. But for the relapses it would be extremely difficult to say that the affection is not typhoid fever with marked bilious symptoms. Weil himself left it an open question whether it is a disease *sui generis*, or a special form of typhus; yet he maintained that it was possibly a peculiar undescribed disease, depending upon a specific cause as yet unknown. He further states that the anatomical changes and functional disturbances of the different organs are to be considered as coordinate effects of the specific infection.

Fraenkel does not believe that all the cases reported as those of Weil's disease are identical in character. The only symptoms common to all are fever and jaundice. He asserts that the cases simply present a group of symptoms which to all appearances are produced by various agencies belonging to the category of septic infective material. Possibly the symptoms arise from intoxication with one or more chemical poisons acting after the manner of ptomaines. In his own case the point of entrance of the poison was a wound; as a rule it has been the intestinal tract. On account, therefore, of this diversity of symptoms and the probability that their cause is not single, Fraenkel recommends that the name "Weil's Disease" should be dropped, as it leads to false inferences.

Fraenkel is probably right in his conclusion that the affection is not a separate entity, but merely one of a group of possible intoxications. It should not be forgotten, however, that Weil's studies and those of others who followed him have made it possible to recognize the group, and that he has thus aided materially in the advancement of medical knowledge.

THE OBLIGATIONS OF HOMŒOPATHIC PHYSICIANS.

In another part of this number of the REPORTER we publish a letter from Judge Barrett, of the Supreme Court of New York, to the *New York Medical Times*, in which he says that a physician designating himself an homœopathist, and called as such to a patient, has no legal or moral right to adopt other than homœopathic means in the treatment of the case.

This opinion is expressed without reserve and Judge Barrett gives his reasons for holding it. These reasons will meet the approval of all representatives of the regular school of medicine, for they are founded upon the belief that practitioners who assume a special designation, and are chosen as medical advisers on that account, ought not to violate the principles which that designation indicates that they hold.

At the present time it is well known that but a limited number of so-called homœopaths believe that the law of *similia similibus curantur* is one of universal applicability. The great majority practise on the same basis as do all intelligent physicians. Although their education gives them a leaning toward the use of certain medicinal preparations which are attenuated or diluted, yet in this they are guided by experience and observation and not by any such theories as Hahnemann promulgated. In fact they have no more right to call themselves homœopaths—though they cling to this title—than they have to call the members of the regular profession allopaths, as though they too followed an exclusive dogma.

The term homœopath, as Hahnemann understood it, does not fit the homœopaths of this day, and the community is deceived insofar as it believes that it does.

We know that there are men in the ranks of the homœopaths who feel the inconsistency of their professions with their practice, and who would be glad to escape from the awkwardness of their position. To such it must be trying to find a learned judge describing the lapses from homœopathy into which they fall as illegal, as well as immoral.

It is with no desire to give offense that we call attention to the way in which the attitude of the so-called homœopaths of our day impresses those who reject all exclusive dogmas, but rather in the hope that a plain statement of it may quicken the zeal of those among them who would be glad to abandon a designation which keeps them separated from the great mass of honest and intelligent medical men, and ties them to men who adopt the name solely as a trade distinction and carry it easily only because their intelligence or their moral sense is defective.

There is only one way in which the breach between the regular school of practice and the homœopaths—a breach which the homœopaths created and maintain—can be closed, and that is by the abandonment of the special name which the latter have assumed and the selection of that noble one which is borne by the members of the regular school.

THE SUPPRESSION OF SMALL-POX.

In the REPORTER, April 27, under "Notes and Comments," we published an account of the way the authorities of Minneapolis, Minn., are said to have dealt with a case of small-pox which was detected in that city, and the measures adopted to prevent the outbreak of an epidemic. As the Editor of *Science*, from which the account is taken, remarks, some of the proceedings reported were absurd, and some were brutal. The former criticism applies to the soaking with corrosive sublimate solution of the clothing of those who vaccinated the quarantined persons. As brutal, it is not unjust to characterize the wholesale quarantining, and the threat to shoot a laboring man if he attempted to escape from imprisonment in a suspected house in which he, with thirty others, was caught.

No doubt the authorities of Minneapolis would justify their conduct by the result; but we think the law in Minnesota must be

peculiar if they could have justified themselves, had they carried out the threat to shoot. The day for shot-gun quarantines has gone by, and we believe that the most that can reasonably demanded of those who are suspected of having been exposed to infection from small-pox is that they shall be vaccinnated, washed thoroughly from head to heels, furnished with new clothing, and kept under *surveillance* for a moderate length of time.

This much we believe would be both feasible and prudent in any city, if a case of small-pox were discovered where none had existed before. We think that intelligent people would consent to the personal inconvenience without complaint, if the city met the expense—as it certainly should. Among the ignorant, resistance would have to be met by persuasion, and, if this failed, by the exercise of as much force as was necessary and legal; but persuasion would always be the best aid of sanitarians, because there is not much law in the United States to warrant such proceedings as are reported from Minneapolis.

HERNIA INGUINO-SUPERFICIALIS.

At the meeting of the Surgeons of Berlin, February 11, 1889, Prof. Küster presented four new cases of this form of hernia described by him under the name of hernia inguino-superficialis. Two of the patients had been operated upon with removal of the atrophied testicle. Two of the patients had double hernia, with atrophy and ectopia of the testicle. In these cases—if they are operated upon—Kuster proposes to save the testicle and to make an artificial tunica vaginalis—as he has already done in one case—although it is impossible now to bring the testicle down into the scrotum.

In the form of hernia described by Küster as hernia inguino-superficialis, the prolapsed bowel lies outside of the muscles of the abdominal wall and is covered only by skin and superficial fascia. This is a condition rarely recognized, and not a case of this sort has ever been reported by an American surgeon. It is closely allied to the inguino-properitoneal hernia which has been referred to in a pamphlet notice in the REPORTER, August 25, 1888, and which is better understood in this country.

Aside from the scientific advantage of accuracy in diagnosis, it is useful to be able to recognize these peculiar forms of hernia, because in some of them a correct diagnosis has a very important bearing upon the treatment to be adopted.

GENEROUS GIFT TO THE EPISCOPAL HOSPITAL OF PHILADELPHIA.—The family of the late George L. Harrison, of Philadelphia, has offered $200,000 to the board of trustees of the Protestant Episcopal Hospital to found and to endow a building for incurables in connection with that institution. Some years ago Bishop Stevens submitted to the Convention of the Diocese suggestions in reference to such an addition to the hospital. He wanted especially an endowment for a ward of such a character. The trustees of the hospital took the matter in hand, and some measures were adopted which brought a response, and a nucleus was formed by donations until the total, some of it given for building and some for an endowment, amounted to something less than $10,000. Now Mrs. Harrison has joined with the four sons of her late husband, Charles C., William W., Alfred C., and Mitchell Harrison, in making the gift to perpetuate the memory of George L. Harrison, one of the best and most generous friends the hospital ever had. It is almost unnecessary to add that the Board of Trustees has accepted the offer.

It is seldom that money is given so generously and so wisely as in the present instance; for instead of expending the whole sum in a building, one-half of the amount is to be reserved as an endowment, so that the building when erected will have ready to its hand the money necessary for accomplishing the good work for which it is intended.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

THE OPERATIONS OF SURGERY. A SYSTEMATIC HANDBOOK FOR PRACTITIONERS, STUDENTS AND HOSPITAL SURGEONS. By W. H. A. Jacobson, F.R C.S., Assistant Surgeon Guy's Hospital, etc. With 199 illustrations. 8vo, pp. 1006. Philadelphia: P. Blakiston, Son & Co., 1889. Price, $5.00.

This handsome book is one of the most admirable works on operative surgery which we have seen for a long time. The author has brought to its preparation a large observation and experience, and a very thorough acquaintance with the methods of other surgeons. His book is comprehensive, and its directions are clear and reliable. The most recent advances in surgery are represented in these pages, although we do not find any reference to operations for the removal of tumor within the canal of the spinal column, a few of which have been performed. It is gratifying to an American reader to find that full justice is done to the work of American surgeons by Mr. Jacobson, and that his book bears no marks of the distance which stretches between his land and ours. This is as it should be, and is no less an element in the excellence of the technical worth of his book, than it is an evidence of the cosmopolitan character of good scientific work.

The book is very well printed and bound, and we have no doubt will meet with general professional favor on both sides of the Atlantic.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

250. Our Insane. The State Hospitals for the Insane Poor. By Hiram Corson, M.D., Conshohocken, Pa., 13 pages.

251. Clinical Studies on the Pulse in Childhood. By John M. Keating, M.D., and William A. Edwards, M.D., Philadelphia. From the *Archives of Pediatrics*, December, 1888. 15 pages.

252. Notes on the Treatment of Acute Coryza. By Frank Hamilton Potter, M.D., Buffalo, N. Y. From the *Buffalo Med. and Surg. Journal*, January, 1889. 5 pages.

253. Femoral Osteotomy for the Correction of Deformity Resulting from Hip-Joint Disease. By Ap Morgan Vance, M.D., Louisville, Ky. From the *N. Y. Medical Journal*, December 1, 1888. 15 pages.

254. Cases in Orthopædic Surgery. By Ap Morgan Vance, M.D., Louisville, Ky. From the *N. Y. Medical Journal*, November 7, 1885. 17 pages.

255. A Case of Hodgkin's Disease accompanied with a possible resulting Paraplegia. By Lewis H. Adler, Jr., M.D., Philadelphia.

256. Zur Behandlung gewisser Formen von Neurasthenie und Hysterie durch die Weir-Mitchell Cur. Von Dr. Josef Schreiber, Aussee-Merau. From the *Berliner klin. Wochenschrift*, 1888, No. 52.

250. Dr. Corson's pamphlet bears on its cover the sub-title: "A plea to the Legislature for a reorganization of the Acts of Assembly regulating the State Hospitals." It contains an argument in favor of the government of hospitals for the insane by Trustees, as exemplified in the Hospital at Norristown, which is one of the best managed institutions of this sort in the world. Our readers are familiar with Dr. Corson's views, because they have been fully explained in the Reporter during the past year; but his pamphlet will prove both interesting and instructive to those who wish to get light on the important subject which it discusses.

251. This pamphlet contains an instructive study of the pulse of infants and small children, in health and in certain organic affections of the heart. The frequency, rhythm, and force of the arterial impulse have been investigated by the writers, and the results of their investigations are recorded systematically, with mention of some rare peculiarities of the pulse which are seldom observed.

252. The readers of the Reporter who have observed the stand it has taken in regard to ventilation of sleeping apartments will not wonder that Dr. Potter's pamphlet commends itself at the very outset to our approval; and those who acquaint themselves with its contents will see, we think, the reasonableness of his suggestions as to best way to prevent and to treat coryza. His directions are simple and sensible, and can be heartily commended to the attention of our readers. An abstract of Dr. Potter's paper was published in the Reporter, January 19.

253. This is a very interesting paper, containing an account of eight cases of deformity of the leg, due to chronic hip-joint disease, in which great relief was afforded by Dr. Vance, by an operation which consisted in partial division of the femur with a chisel, followed by breaking the bone—the whole being done subcutaneously—and placing the limb in a good position and retaining it so until bony union took place. The improvement in some of these cases was almost marvellous, and it is no wonder Dr. Vance has a high opinion of an operation which in his hands has yielded such good results.

254. This paper by Dr. Vance antedates the one noticed just before by three years, and contains accounts of five cases illustrating a variety of orthopædic difficulties and the way in which he treated them. One was a case of extreme valgus due to infantile paralysis, in which an artificial ankylosis of the ankle-joint was produced. Two more cases illustrate similar procedures at the knee and ankle respectively; and in two he partly divided and partly broke the femur to correct deformities resulting from old hip-joint disease.

255. Dr. Adler's article contains a good report of a well-studied case of Hodgkin's disease, which was under the care of Prof. Horatio Wood at the Hospital of the University of Pennsylvania.

256. Dr. Schreiber's paper contains an admirable discussion of the value of Dr. Weir Mitchell's method for the treatment of neurasthenia, and of the modifications which should be made in it in certain cases. The discussion shows that Dr. Schreiber has not been a blind follower of the routine of this method, but has grasped its underlying principles, and recognized the fact that some of its details would be absolutely damaging to some patients to whom other parts of it would be very beneficial.

CORRESPONDENCE.

Formula for Boro-glyceride.

To the Editor.

Sir: Will you be good enough to give me through the Reporter the formula for the preparation of boro-glyceride, so much and so successfully used in middle-ear diseases and to which reference is so often made in The American System of Gynæcology? I desire the formula for the original boro-glyceride, and also the proportion of it in solution for use.

Yours truly,
S. H. Barham, M.D.

Lone Oak, Texas,
April 17, 1889.

[The preparation called Boro-Glyceride is regarded by some chemists as a mere chemical mixture, and by others as a true compound However this may be, its mode of preparation is as follows: 92 parts of glycerine are heated in a weighed porcelain capsule to a temperature not exceeding 302 degrees Fahrenheit, and 62 parts of boric acid are added in portions, constantly stirring. When all is added and dissolved, the heat is maintained at the same temperature and the stirring is continued, breaking up the film which forms on the surface. When the mixture has been reduced to a weight of 100 parts, it is poured on a flat surface, previously coated with a very small quantity of petrolinum and allowed to cool, when it is cut into pieces and transferred to bottles or jars.

Boro-Glyceride is a very hygroscopic and is best kept by being combined with, or dissolved in, an equal part or two parts of glycerine. This is the form in which it is usually employed in gynecological practice for tampons, etc. It is a sticky, tenacious liquid, which has to be kept in a very wide-mouthed bottle, or it is almost impossible to get it out.—Editor of Reporter.]

NOTES AND COMMENTS.

What a Patient May Demand of a Homœopath.

On March 11, 1889, the *N. Y. Medical Times* addressed a letter to the Hon. Geo. C. Barrett, Judge of the Supreme Court, asking him to answer the following question: "Has a physician designating himself an 'Homœopathist,' and called as such to a patient, any legal or moral right to adopt other than homœopathic means in the treatment of the case?"

To this Judge Barrett replied under date of March 13, 1889: "I have your note of the 11th inst., asking my opinion upon a question of professional ethics. In my judgment there can be but one answer to your question, and that is in the negative. If I call in a medical man who designates himself a 'Homœopathic physician,' it is because I do not wish to be treated allopathically, or eclectically, or otherwise than homœopathically. There is an implied understanding between myself and the homœopathist, that I shall receive the treatment which, by tradition and a general consensus of opinion, means small doses of a single drug administered upon the principle of 'similia similibus curantur.' If there is to be any variation from that method, I have a right to be informed of it and to be given an opportunity to decide. Common honesty demands that before a confiding patient is to be drugged with quinine, iron, morphine or other medicaments, either singly or in combination, he should be told that the 'Homœopathist' has failed, and that relief can only be afforded by a change of system. An honest 'Homœopath,' who has not succeeded, after doing his best with the appropriate homœopathic remedies administered on homœopathic principles, should undoubtedly try anything else which he believes may save or relieve his patient. But when he reaches that point, the duty of taking the patient into his confidence becomes imperative. The patient may refuse to submit to the other system, or he may agree but prefer a physician whose life has been specially devoted to practise under that other system. He may say to the 'Homœopathist,' you have failed, but I prefer to try another gentleman of your own school, before resorting to a system that I have long since turned my back upon. Or he may say, well, if homœopathy can not save me, I prefer to go to headquarters for allopathic treatment.

All this, gentlemen, is the logical sequence of the particular designation 'Homœopathist.' There may, of course, be gentlemen who in a general way favor the principle of small doses and 'similia similibus curantur,' to whom it would not apply. But such a physician would not stamp his school upon his work as a practitioner. If I call in such a man, I mean a physician pure and simple—calling himself neither homœopathist nor allopathist—the implied understanding is that I entrust myself to his best judgment in all respects. Such a man may be a graduate of the College of Physicians and Surgeons, and I will have no cause of complaint should he in an exigency deem it appropriate to administer the third potency of aconite. Or he may be a graduate of a college founded under homœopathic auspices, and yet I can not object if he thinks the occa-

sion demands twenty grains of quinine. But if a physician calls himself allopathic and is summoned as such, it would be a fraud to resort to homœopathic treatment without full disclosure to the patient of what was proposed. If, however, we are to have a class of men who purpose, in the interest of humanity, to utilize the best that they can find in any and every school, 'pathist,' as a designation of fixed methods of practice, must be ignored, and the broad and noble title 'physician,' in its unreserved sense, be revived and substituted.

The patient will understand, when he sends for one of this class, that he is to have the physician's best judgment in the unprejudiced use of the ripest fruits of modern discovery in every field. I see that I have done more than simply answer your question. But I am sure you will pardon a layman for taking advantage of the occasion to intimate the need of greater clearness of professional attitude—both as a matter of justice to the patient and as due to the integrity of the physician."

Treatment of the Eczema of Dentition.

According to M. E. Besnier, eczema of dentition is a reflex eczema from the face, and at times from the back of the hand and wrist, with tenderness of the gums and salivation. There are three indications in its treatment: (1) to allay the itching of the gums; (2) to control insomnia; (3) to cure the local condition. To allay the irritation of the gums, he recommends frequent touchings and frictions of the gums with a finger dipped in the following solution:

Hydrochlorate of cocaine	gr. $\frac{5}{6}$
Bromide of potassium	gr. viiss
Distilled water,	
Glycerine	of each ♏cl

M.

To control insomnia, he employs teaspoonful doses in soup, every hour, of the following mixture:

Bromide of sodium	gr. ivss–viiss
Syrup of orange flowers	f ℥ iss

For the local condition he prescribes the following ointment:

Oxide of zinc	gr. cl
Vaseline	℥ iv

In addition, Besnier recommends to cover the affected regions with a mask of linen or muslin coated with gutta percha. In some affected parts a sheet of mackintosh may be used.—*Gazette Hebdomadaire*, March 29, 1889.

Ammonium Chloride in Fumes for Inhalation.

Dr. P. W. Maxwell says in the *Dublin Journal of Medical Science*, March, 1889, that his experience with ammonium chloride has been confined to catarrhal conditions of the nose and pharynx. He has found it most useful in cases in which the secretion is scanty or nearly absent, and also in those in which, though abundant, it is tenacious and difficult to dislodge. In such cases the greatest immediate benefit seems to be produced by a warm solution of the salt used as a nose wash; but he is inclined to think that, where repeated applications are necessary, the fumes produce in the long run the most good. For the production of the fumes he describes an apparatus which consists of a wide piece of glass tube, resembling the cylinder of an ordinary glass syringe; this tube is placed horizontally on two wooden supports. About fifteen grains of ammonium chloride are introduced by a spoon through the wide end of the tube, and are placed in a little heap in the centre. The base is then lightly stopped with cotton wool. A lighted spirit lamp placed beneath the tube volatilizes the salt. A piece of rubber tubing with a glass mouth-piece is attached to the narrow end of the tube, through which the fumes are inhaled. A current of cold air rushing in by the large end of the horizontal tube mixes with the fumes and reduces their temperature, so that they are not more than slightly warm. These fumes, he says, are neutral from first to last. When it is desired, they can be medicated with oleum pini sylvestris, eucalyptus, etc., by dropping about five minims of the oil upon the wool at the wide end of the tube.

Atropine in the Prevention of Shock.

At the meeting of the New York Surgical Society, Jan. 9, 1889, Dr. Lewis A. Stimson recommended the hypodermic injection of from $\frac{1}{75}$ to $\frac{1}{100}$ of a grain of atropine previous to giving ether for an operation, and instanced cases in which its good effects were shown. He has used atropine for this purpose for five or six years, having first observed its control of the inhibitory action on the heart in certain physiological experiments. How much influence it may exert it is not always easy to determine, but he believes it to be of great value.—*New York Medical Journal*, March 9, 1889.

Hysteria in Infants.

Prof. Grancher has recently stated that the diagnosis of hysteria in infants is often very difficult, as the disease presents anomalies not usually found in that affection in adults. The most distinctly marked symptoms are: very sudden convulsive crises, quick throwing back of the head, convulsive movements of the eyes, jerking strokes of the limbs, and pharyngeal spasm. The attacks usually last about half a minute; there does not appear to be a complete loss of consciousness. At first sight, such attacks would be regarded as epileptic. The general condition of the patient and the frequency of the accessions must decide the matter. Epilepsy soon involves the general health to a very marked degree, the crises increase in number and the patient becomes progressively dispirited. In infantile hysteria, on the contrary, these conditions do not exist, and we often find the child in high spirits very soon after the attack.—*New York Med. Abstract*, April, 1889.

Clinical Observations on Gonorrhœa.

Drs. John P. Bryson and Edwin C. Burnett communicate a very interesting paper to the *Journal of Cutaneous and Genito-Urinary Diseases*, April, 1889, based upon a study of a very large number of cases, 1394 of which were seen in dispensary practice; for the latter reason they regard their observations as not justifying definite conclusions regarding the average duration of gonorrhœa. They incline, however, to accept the generally expressed opinion of clinicians that, when treated according to the so-called "methodical" plan, the great majority of patients with gonorrhœa apparently get well in from six to eight weeks. This result they find to occur most frequently when all local treatment is abstained from in the increasing and stationary stages of the disease, and is reserved for the decreasing or subacute conditions, every effort being made to limit the inflamed areas to the anterior portion of the duct.

They conclude that gonorrhœa is a specific disease of which the gonococcus of Neisser is the essential etiological factor. The abortive treatment is held to be both inefficient and harmful. They recognize in the disease a marked tendency to persist in the chronic stage, and this tendency appears to them to be increased by the use of topical treatment in the first and second stages. In their opinion the internal administration of remedies (especially balsam of copaiba and oil of yellow sandal wood), combined with proper hygienic and dietetic regulations, does most to shorten the duration of the disease. In the third or declining stage mild vegetable and mineral astringents seem to be of service.

Treatment of Tetanus by Absolute Rest.

Prof. de Renzi, of Naples, has carried out the treatment of tetanus by absolute rest in four cases, and has obtained a successful result. He was led to try the treatment through noticing that a frog poisoned with one-twentieth milligramme of strychnia and exposed to the influence of light and sounds could not be saved; but if it were kept in absolute rest, it survived.

The following is the treatment adopted: the patient's ears are stopped with wax and cotton and he is brought into a very quiet and dark room, into which no noise is allowed to penetrate. It is impressed upon the patient that his recovery depends upon absolute quiet. The room is entered only every four hours, and with a dark lantern. Nourishment is fluid and is given by the mouth, so that chewing will be avoided. When there is marked pain some belladonna and ergot are given. Of five patients so treated four recovered.—*Wiener med. Presse*, March 17, 1889.

Digestion of Live Tapeworm.

As long ago as 1780, Dr. Masars de Cazelles described a tænia fenestrata. Drs. Notta and Marfan published notes of a suspected specimen two or three years ago. With regard to this specimen, Dr. Danysz gives, in the *Journal de l'Anatomie et de la Physiologie*, a series of observations by which he endeavors to show that the parasite was a tænia saginata, and that the perforations commence as little superficial erosions, which gradually extend through the entire thickness of the segment. Apparently the process begins by fatty degeneration of the cuticle of the tænia. The cuticular layer of the diseased segment breaks down at the points where the degeneration has taken place. The interior of the segment is then exposed to the digestive fluids of the host. In this way holes are soon made. Several segments may be reduced to the form of oblong frames. Dr. Danysz illustrates this singular change due to digestion of the live parasite.—*British Med. Journal*, Feb. 16, 1889.

A Dangerous Chlorate of Potassium Prescription.

A pharmacist writes to the *Bull. com.*, January, stating that he often gets a prescription as follows: Chlorate of potassium, 5 gm. (gr. 75); distilled water, 120 gm. (4 fl. oz.), simple syrup, 30 gm. (1 fl. oz.), a dessertspoonful every half-hour. "Children who take this," adds the pharmacist, "*always die.* M. Brouardel cites six cases of death in children after using a similar potion. Can I refuse to dispense this mixture?" The editor says the pharmacist cannot refuse; he can only state the facts to the doctor, "who will be likely to attribute the cause of death to the gravity of the disease." He adds: "Physicians, on account of the scant information we have as to the physiological action of chlorate of potassium, use this medicament with the same imprudence and the same indifference as they have formerly shown."—*American Journal of Pharmacy*, April, 1889.

Galvanism in Dysmenorrhœa and other Pelvic Pains.

Dr. Franklin H. Martin, Professor of Gynecology in the Post Graduate Medical School of Chicago, discusses in the *North American Practitioner*, April, 1889, the employment of galvanism in the treatment of dysmenorrhœa and other pelvic pains. He employs a current-strength of 100 milliampères. Externally he employs what he calls "a large animal membrane abdominal" electrode, large enough to cover the whole surface of the abdomen between the pubes and umbilicus. The vaginal electrode described consists of a metal exposure of 16 square cm., surrounded with wet absorbent cotton; it is crowded well up into the space between the uterus and the vaginal walls on one or the other side of the cervix, as may be indicated by the requirements of the case. With the electrodes held firmly in position, the current is gradually turned on until it reaches a strength of 100 milliampères. Here it is allowed to rest for five minutes, when it is gradually turned off, and the treatment finished.

Dr. Martin reports three cases in which this treatment was adapted to the relief of pain, and expresses the opinion that in certain conditions, in which pain is often the predominant symptom, galvanism will prove an infallible and prompt remedy. His propositions are:

1. Do not advise the removal of an ovary for persistent pain, until galvanism has been systematically and thoroughly applied, if any of the following conditions are suspected as a cause: (*a*) chronic ovaritis, either with or without hypertrophy; (*b*) where inflammatory deposits, either with or without adhesions, surround one or both organs; (*c*) ovarian neuralgia; (*d*) all pain coincident with menstruation; (*e*) in all cases of ovarian pain not known to be the result of active, acute inflammation; septic or specific inflammation; and cystic tumors.

2. Galvanism is a sure remedy for all pain resulting from tubular diseases, except when septic or specific inflammation is the cause, or the presence of pus is demonstrated.

3. Galvanism is positively indicated in dysmenorrhœa or other pelvic pain, when a result of chronic metritis; when a result of hyperplastic enlargement of the uterus; when a result of fibrous or other non-malignant growths of the uterus.

4. Galvanism is emphatically indicated in pelvic pain when a result of old pelvic exudates of all kinds, provided acute inflammatory action is absent and the presence of pus is not suspected or demonstrated.

5. Galvanism is indicated in pelvic pains, arising from reflex disturbances, or hystero-neuroses, the condition well defined by Engelmann as "a phenomenon which simulates a morbid condition in an organ that is anatomically in a healthy state."

6. Galvanism is indicated in dysmenorrhœa, when the result of cervical lacerations, with unyielding cicatrized plugs; when the result of cervical endometritis or uterine vegetation.

Commencement of the Medical and Dental Departments of the University of Pennsylvania.

The one hundred and fifteenth annual commencement of the Medical and Dental Departments of the University of Pennsylvania was held May 1, 1889, and the degree of Doctor of Medicine conferred on 124 graduates, and the degree of Doctor of Dentistry on 58 graduates. The valedictory address was delivered by Dr. Osler, the retiring Professor of Clinical Medicine. A portrait of Dr. Agnew, the retiring Professor of Surgery, was presented to the University by the three undergraduate classes of the Medical Department, and accepted on behalf of the Trustees by Dr. S. Weir Mitchell. In response to numerous calls, Dr. Agnew spoke a few earnest words to the graduating class, and was nearly overcome by his deep emotion.

NEWS.

—The Iowa State Medical Society will meet in Keokuk, May 15, 16 and 17.

—The Townsend Chapel of Bellevue Hospital, New York City, was dedicated April 22.

—Dr. James L. Manney, the son of Dr. James Manney, died in Wilmington, N. C., March 18.

—Dr. Lallement, Professor of Anatomy in the Medical Faculty of Nancy, recently died of apoplexy.

—The annual meeting of the Missouri State Medical Association will be held in Springfield, May 21.

—It is stated that the Roosevelt Hospital, New York City, will receive $350,000 from the estate of the late Mr. William J. Syms, to be used for building and maintaining a new operating theatre.

—The President of the Board of Heath of Sanford, Florida, stated April 23, that a case of yellow fever existed in that city. Every precaution has been taken to prevent a spread of the disease.

—Dr. W. F. Wilson is reported to have died in Denver, Colorado, April 19, from an overdose of morphine taken to induce sleep. He was only 29 years of age, but had been troubled with insomnia.

—The Kansas City Medical College held its twentieth annual commencement on March 11, and conferred the degree of Doctor of Medicine on 18, and the degree of Doctor of Dentistry on 11 graduates.

—Mr. John G. Borden, a winter resident of Florida, has, according to the *New York Medical Journal*, April 27, offered a prize of $1000 to the city within that State which shall be found in the most cleanly condition on July 1.

—Dr. R. C. Word, the managing editor of the *Southern Medical Record*, had his dwelling, furniture, library, instruments, his lecture notes, the manuscript of a work nearly ready for the press—all destroyed by fire on March 16.

—The Health Commissioner of Baltimore was notified, April 23, that at Santos and Rio, the ports from which the coffee importers of Baltimore receive nearly all their coffee, the yellow fever is raging more virulently than ever before. At the time of the last report from Rio there had been 186 deaths from yellow fever in four days.

HUMOR.

A GLASS EYE has one compensation—everybody else can see through the device if the wearer can't.—*Life.*

THE POOR OLD KING of Annam is dead. His is the most notable case of suspended Annamation on record.—*Philadelphia Press.*

A SMALL BOY sojourning on the coast of Maine sent the following clipping to his father in Boston:

Examiner—"What would you do in the case of a man with clammy sweats?"

Budding Sawbones—"Advise him to give up clams."

The boy appended the following:

"Dear papa, I thought you would appreciate the above, as you are having the sweats and I am having the clams."—*Western Medical Reporter.*

OBITUARY.

THOMAS S. SOZINSKEY, M.D.

Dr. Thomas S. Sozinskey died at his home in Philadelphia, April 19. He was born at Cabery, County Derry, Ireland, about 37 years ago. In 1869 he came to Philadelphia, where he has since resided. In 1872 he was admitted to the degree of M.D. by the University of Pennsylvania, which, the following year, also conferred upon him the complimentary title of Ph.D. He was for years a member of the Masonic Order. Three children survive him.

RESOLUTIONS ON THE DEATH OF DR. GROSS.

At a special meeting of the J. Aitken Meigs Medical Association, held April 22, 1889, the following minute was made: The ranks of the remaining few of the instructors of the members of this Association having been invaded by death, it is in grateful appreciation, Resolved, That we will cherish the memory of Dr. Samuel W. Gross, as a talented teacher, whose precepts then inculcated guide us in our daily pursuits; and that, together with the medical profession at large, we mourn the loss of a *savant* whose impressive teaching, erudite writing, and originality of thought and operative skill have made him a master in surgery.

J. MOORE CAMPBELL, *President,*
M. H. BOCHROCH, *Secretary.*

THE SUSTAINED SUPREMACY

OF

Fairchild's Pepsin,

In ACTIVITY, PERMANENCE and GENERAL EXCELLENCE

Has won for this product a wide use and recognition in all the principal markets of the world.

We guarantee it to be unchangeable, to maintain its activity and quality under all ordinary commercial conditions; it is therefore, by far the most available for the dispensing counter, as well as in the manufacture of every form of pepsin preparation.

Under exactly parallel conditions, with any proper percentage of acidity and with any proportion of such acidulated water to the albumen, Fairchild's pepsin is positively superior to any pepsin known.

It will, under absolutely comparative conditions, grain for grain, digest more albumen than any other pepsin made.

We will be pleased to send samples to any physician who may wish to ascertain for himself the relative activity of Fairchild's pepsin, or to submit it to any practical trial.

Prices and complete information upon application.

FAIRCHILD BROS. & FOSTER,

New York. Chicago. London.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO.,

PHILADELPHIA.

SPECIAL NOTICE.

For the accommodation of Physicians who are unable to leave home for prolonged periods,

THE PHILADELPHIA POLYCLINIC

issues tickets good for three months, entitling the holder to attend one clinic weekly.

The fee for such special tickets is the same as for the ordinary tickets, which are good for daily clinics for six weeks from date of issue. For any one branch, $15.00.

General ticket for all clinical branches, $100.00. For announcement giving full particulars, address

L. W. STEINBACH, Secretary,
N. W. Cor. Broad and Lombard Sts.
Philadelphia.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

PYURIA. CONVALESCENCE FROM TYPHOID FEVER.[1]

BY JAMES B. WALKER, M.D.,
PHILADELPHIA.
PROFESSOR OF THEORY AND PRACTICE OF MEDICINE IN THE WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA.

Pyuria.

This patient is thirty-three years old and a glass-blower by occupation. He came into the house a few days ago with a fever, a cough and a pain in the right side rather low down, and in the back.

His history is as follows: Three weeks ago the pain began in the right side without apparent cause, and has continued off and on since. The past week it has become more severe, and cough has appeared. There is a little expectoration of a yellowish color, which occurs for the most part in the morning. The pain has remained on the right side, but it occasionally shoots to the left. The patient complains, at times, of pain in the cardiac region. He has been losing flesh for several months. He has no appetite; his bowels are regular. He has complained for two weeks of ringing noises in the ears. He has never been healthy; has had malaria almost every spring, and had typhoid fever two years ago. He was in the hospital six years ago with secondary syphilis, but he has had no symptoms of that disease since. His mother died at forty, and a sister at twenty—both with some heart trouble. One brother was living and well when last heard from.

The temperature on admission was 104.6°. It fell to 99.4°, then to 98.2°, and this morning it is 98.8°. His respirations have been in the neighborhood of 26, and his pulse about 92, the respiration being increased relatively to the pulse.

His urine is amber-colored, acid, with a dense sediment which consists chiefly of pus and epithelium. It contains one-eighth per cent. albumin, but no sugar. By pressing over the floating ribs near their spinal

[1] Delivered at the Philadelphia Hospital, April 24, 1889.

extremities, we find a tenderness which is exaggerated by counter-pressure from the back. This tenderness exists below the level of the ribs in the right lumbar region, but does not reach the umbilical region. There is slight tenderness on the left side also.

When he first came in, we supposed from his history of cough, his high temperature, and pain in the side that we would find pneumonic trouble, although the pain was low down; for the pain in pneumonia is very indefinite in location. Examination of the lung, however, showed that it was not involved.

Excluding, therefore, pneumonia and pleurisy, the urine was examined, with the result given. The pain and tenderness were in the region of the kidney. Generally the location of tenderness over a viscus is sufficient to refer the disease to that organ, but sometimes pain is radiated from its origin, and nerves at a distance are made sensitive. I have seen a case in which a renal calculus gave rise to such intense pain in the gluteal region that a diagnosis was made of lumbago and muscular rheumatism of the thigh. With, however, tenderness over the kidneys and the presence of acid urine containing pus, we have pretty clearly located the disease in the kidney itself. A chronic catarrh of the lining membrane of the bladder, when, as is usually the case, bacteria are present, will promote alkaline, ammoniacal changes in the urine; but if with pyuria the urine is persistently acid, it is almost pathognomonic of renal trouble.

What is the kidney trouble that can cause pyuria? It is a calculus more frequently than anything else, which gives rise to surgical kidney—but not always. We had at one time in this house a very interesting case, which taught us a lesson. The patient had a history somewhat similar to this man's. He would have high temperature, with severe pain in the region of the kidney. Then he would void a considerable amount of urine containing pus, and would experience relief from the fever for twelve to fifteen days; at the end of that time he would again have another attack lasting twenty-four or forty-eight hours, followed in turn by another remission. It was supposed, therefore, that there was a renal calculus blocking up the pelvis of the kidney and acting as a ball-valve.

It occurred to us, however, that there might be bladder trouble, and Dr. White, at my suggestion, examined the man and found strictures of the urethra from an old gonorrhœa. After having had the strictures dilated and after taking lithium borate and other antacids and diluents to keep the urine unirritating, the man recovered. Now, in that case, three of the visiting staff had agreed that it was wise to perform an exploratory operation and see if there was a stone in the pelvis of the kidney.

The case has impressed upon me the importance, in these cases, of always examining the bladder and urethra. I have asked, therefore, that it be done in the present case. In the meantime we must keep the urine in an unirritating condition. In most cases of the kind described, the urine is so acid that a small calculus of uric acid forms in the pelvis of the kidney and increases the irritation. The indication is, therefore, to prevent the further production of this form of calculus by rendering the urine alkaline. With this in view, that salt which is most solvent to uric acid should be used. It is probable that the uric acid calculus, once formed, is not soluble by the use of any known remedy which can be administered by the mouth and excreted by the kidney. But we can, at any rate, prevent the formation of new calculi. We must not, on the other hand, make the urine so strongly alkaline as to produce secondary alkaline deposits on the calculus. Therefore we should keep the urine in a very faintly alkaline or neutral condition.

Lithium salts are better than potassium salts for prolonged use; though, if you have a very severe case, I would recommend the occasional substitution of the potassium salts, because they act more rapidly, giving potassium bromide for nervous symptoms combined with potassium citrate or acetate for its action on the urine.

Lithium carbonate is given in three to five grain doses in pill form four times a day. If five grain doses are given, divide them into two pills each, for five grains in one pill would form a bolus too large to swallow. You may use in addition one of a number of alkaline waters, such as Waukesha, Buffalo Lithia, Londonderry or Lincoln Water. The increased amount of water taken by the mouth will in itself favor the washing out of the calculus, provided it be removable in this way. If not, surgical treatment alone will accomplish its removal.

The production of an offensive alkaline urine which undergoes ammoniacal changes, may be prevented by giving the patient boric acid, which tends to make the urine acid. The action of two grains of boric

acid more than counteracts the alkaline tendency of three to five grains of lithium carbonate. It is not, however, the mere acidity of the urine that causes the deposition of calculi, but the presence of uric acid. Find out by experiment, therefore, how much alkali is necessary to make the urine slightly alkaline, and then administer in addition two to five grains of boric acid every day to prevent the decomposition of the urine, which otherwise would be likely to lead to extensive suppuration of the ureters and bladder. The sound revealed the presence of a decided stricture in this case, which may prove that the entire trouble is of gonorrhœal origin.

Convalescence from Typhoid Fever.

Case I.—This patient came before you three weeks ago with typhoid fever. His temperature was then running a pretty even rate, ranging from 102.3° in the morning to 103.2° in the evening. Since that time the temperature has showed very little variation until seven days ago, the twentieth day after admission, when it fell to 99°; and twenty-four days after admission, that is, day before yesterday, it fell below normal.

He had been sick for about two weeks before admission. He had not gone to bed until he was brought to the hospital. His pulse has rarely been above 100, and the temperature has not varied greatly between the above morning minimum and evening maximum. The case has gone on very nicely. When I showed the patient to you at first, he had quite marked diarrhœa—three or four movements a day—but since then he has had not more than two a day, and sometimes none at all. There has been no complication except bed-sores, which are fortunately rare in typhoid fever at present. All over the right trochanter major there is a puffy angry sore. There was also one over the sacrum, which has healed except a very small centre that is burrowing, with the formation of a little sanious pus. The sore should be syringed out with some antiseptic solution, and possibly it will need free incision.

Dujardin-Beaumetz, in his "Clinical Therapeutics," states that he accidentally used a one per cent. solution of chloral on a bed-sore, and with such good results that he has continued to use it since. As the bed-sore upon the hip did not yield very readily to chloral treatment, cinchona ointment (ʒi of the powdered bark to ʒi of simple ointment) was used.

In typhoid fever, especially in the nervous form, bed-sores are apt to occur in spite of the most careful treatment. To protect against bed-sores, we may make pads of elastic wool or cotton, or we may use a water-bed or cut a hole in the mattress so as to distribute the weight upon the thigh and the body above. If the threatened bed-sore is seen in time, we may prevent it not only by relieving pressure but by stimulating applications, such as alcohol, salt and whiskey, or alum solutions; but the removal of pressure is better than any washes that can be used. A doe-skin plaster, a quarter to half an inch thick, makes an excellent protective; but the trouble with this, as with most plasters, is that, unless carefully watched, a crease is formed which increases the irritation. It is better, therefore, to have the surface uncovered as long as it is unbroken.

This patient's tongue is now clearing off, though there is still some fur on it. His pulse is still dicrotic. We may not yet change the quality of his food, although his temperature is returning to normal. The use of vegetable foods in typhoid fever is very much to be deprecated. The starchy preparations should be especially avoided, because they are digested chiefly in the small bowel—which is the part of the intestine principally involved in typhoid fever—and also on account of their tendency to over-distend the bowels with gas, which embarrasses the heart and respiration and may even cause rupture of the intestine.

Rice is the starch first to be resorted to in these cases, as it does not produce much gas; but the solid animal foods, such as a soft boiled egg, a piece of tenderloin steak—nicely broiled and well masticated, and the pulp not swallowed at first—should be used early in convalescence.

During the disease, milk and meat broths—but *not* soups to which flour and other vegetable starchy matters have been added—should be employed. Beef and mutton are preferable to chicken and veal. Chicken broth is perhaps more laxative than any other meat broth.

Case II.—The next patient is a farmer, thirty-nine years old. Five weeks ago, without any apparent cause, he had a chill followed by pains all over his body, especially in the abdomen and head, which have continued and have grown worse. He went to bed and has remained in bed most of the time since. The bowels were sometimes constipated, sometimes loose, until a week ago, since which time he has had diarrhœa

constantly, to the extent of having six or seven stools a day. There have been no hemorrhages of any kind.

On admission, his temperature was 101.6°, pulse 97, respiration 19. Since then his pulse has ranged from 76 to 84. His temperature ranged, for the first two days, between 101° and 102°, and then fell to normal—rising, however, to 100 in the evening—and since has risen and fallen, but has not been far from normal.

His tongue has improved quite decidedly since day before yesterday. It has now lost its dryness, but is somewhat coated and has a red tip and edge. His skin is normal to the touch. His pulse has a fair volume, is soft, very compressible, and slightly dicrotic. On whipping the deltoid muscle, contraction is evoked. This is rather a painful experiment, but it is said to be suggestive of typhoid fever. I have found it in all the cases of typhoid fever in which I have examined for it, but I have not tested to see whether it is present or not to the same degree in other weak conditions. There are the remains of a spot in the centre of the abdomen, which do not disappear on pressure. This is the case frequently with old typhoid spots. On Monday this spot disappeared on pressure, and was suggestive of a typhoid eruption. The tenderness over the abdomen is great, and is not confined to the right iliac region. There is no tympanites, but the abdomen is rather scaphoid.

He had been eating pretty much everything before he came into the house, so that his intestines are in a condition of widespread irritation.

The improvement in his condition just mentioned occurred under the administration of small doses of calomel and ipecac—one-twelfth of a grain each—repeated till the bowels moved. These remedies are indicated when the secretions are lacking and the skin and the tongue are dry, even if there is diarrhœa.

This spring there has been almost an epidemic of typhoid fever in Philadelphia, and many other cases have seemed to be on the verge of having typhoid fever. You know the general idea is that the typhoid fever germs, on entering the system and finding a lodgment, invariably develop and produce a well-marked attack of typhoid fever. The Germans believe that, although the system may not have the power to resist the entrance of germs, it may be able to prevent the full development of the disease. In a number of cases when headache with dryness of the tongue and skin have manifested themselves, I have given calomel with ipecac or soda, not repeating this treatment unless the same symptoms recurred. This I have followed by quininæ sulph., gr. iss; caffeinæ, gr. ss, in pill form, every four hours. It is continued for about seven days, and additional doses of caffeine are given in the intervals, if they are necessary to control headache. Generally, under this treatment, the appearances of threatened typhoid have passed away, but I do not say that I have averted typhoid fever in any case.

I do not like to use antipyrin and antifebrin for the relief of headache in a case of threatened typhoid. They are depressing and have to be used in almost as large doses for headache as for their antipyretic effect. By avoiding them early in a threatened attack they may be reserved for their more important effect later, should the rise in temperature demand their use; although I am not in favor of their employment as antipyretics, unless the indications for them are urgent.

COMMUNICATIONS.

REMARKS UPON THE TREATMENT OF THE OPIUM HABIT AND KINDRED AFFECTIONS.[1]

BY J. C. WILSON, M.D.,
PHILADELPHIA.
PHYSICIAN TO THE HOSPITAL OF THE JEFFERSON COLLEGE, ETC., ETC.

There are clear indications that the habitual abuse of the more subtile and pernicious narcotics is a growing evil. Were the increase of the evil open to question, the manifest prevalence of these habits is wide enough to excite serious apprehension among those interested in social problems, and to render any apology for the discussion of the subject in this Society is unnecessary. Unlike alcohol, the addiction to which, however secret at first, sooner or later betrays itself by unequivocal signs, opium, chloral, and others of the group give rise to a vice essentially secret. The practitioner who is on the alert finds the consumption of some such drug, often in large amounts, to be the underlying cause of a noteworthy proportion of the cases of chronic invalidism that come under observation.

[1] Read before the Philadelphia Neurological Society, April 22, 1889.

The victims of these habits occupy a much higher social level than the victims of alcoholism. A large proportion of them are persons of intelligence and refinement. We find among them men of letters, professional men, especially physicians, in unfortunate preponderance, while the statistics of numerous observers point to even greater prevalence of the habit among women.

A certain proportion of the cases are incurable. A considerable number of them, although not permanently curable, may under proper management be freed from the vice for more or less prolonged periods. A third group comprises individuals who have fallen into vicious habits of this kind rather through unfortunate circumstances than through any defect of nervous organization, and who are, therefore, capable of permanent restoration to health. For these reasons the consideration of the subject of habitual narcotism merits the attention not only of those in the profession who have especially devoted themselves to the study and treatment of nervous diseases, but also of those engaged in general medical work.

The diagnosis of the opium habit is in many cases attended with considerable difficulty. Many *habitués*, it is true, do not hesitate to admit the real cause of their symptoms. Others, while seeking to conceal it, do so in such an indifferent manner that detection is not difficult. But the greater number for a long time sedulously conceal their passion not only from their friends, but also from the physician whom they select voluntarily or at the solicitations of those interested in them. If inquiries be made upon the subject, they deny the habit altogether, often with vehement protestations. If forced to admit it, they are very apt to mis-state the amount taken or the frequency of the dose.

As a rule, to which there are, however, not infrequent exceptions, emaciation is marked, the appetite is diminished and variable, the pulse is small, the circulation feeble, the respiration often sighing, the pupils occasionally strongly contracted, constipation is present, often alternating with diarrhœa. When to these conditions, for which no cause can be found upon careful examination, there are added marked change in disposition, periods of unaccountable dulness alternating with unusual vivacity and brightness, especially insomnia alternating with periods of prolonged and heavy sleep, the abuse of narcotics may be suspected. If the hypodermic syringe be used, the wounds made by the needle confirm the diagnosis. These punctures are usually found in groups upon the thighs, legs, arms, or abdomen. Close inquiry into the habits of the patient, who either goes himself, or sends at short intervals to some neighboring apothecary, for unusually large quantities of opium, morphia, or other narcotic drug, is sometimes necessary to confirm the diagnosis.

The diagnosis of the chloral habit is attended with much less difficulty than that of the morphine habit. In the first place, there is general and often serious derangement of health without adequate discoverable cause. The appetite is poor and capricious, the digestion imperfect and slowly performed; jaundice of variable intensity, often slight, sometimes severe, occurs in many cases; the bowels are not as a rule constipated. Dyspnœa upon slight exertion is, in the absence of pulmonary, cardiac, or renal trouble, of diagnostic importance. The circulation is as a rule feeble; disorders of the skin, persistent or easily provoked conjunctivitis, and a tendency to hemorrhages from mucous surfaces also occur. When with these symptoms, irregularly grouped as they are apt to be, we find a tendency to recurring attacks of cerebral congestion, persistent or frequently recurring headaches, and the evidences of subacute peripheral neuritis, the abuse of chloral may be suspected. The pains of the limbs are almost characteristic; they are acute and persistent, neuralgic in character, but not localized to special nerve tracts; they are more common in the legs than in the arms and occupy by preference the calves of the legs and the flexor muscles between the elbows and wrists; they do not implicate the joints, are not aggravated to any great extent by movement, and are often temporarily relieved by gentle frictions. The pains of chloralism have deen described as though produced by encircling bands above the wrists and ankles. The suspicion of addiction to chloral becomes the more probable if there be a history of prolonged painful illness or prolonged insomnia in the past. This suspicion is confirmed when we encounter at the same time perversion of the moral nature, enfeeblement of the will and of the intellectual forces. It is rendered positive, notwithstanding the denials of the patient, by the discovery of the drug or the prescription by means of which it is procured.

The same diagnostic criteria are available in cases of vicious narcotism from cocaine and cannabis indica.

The treatment of these affections naturally ranges itself under two heads: (A) the prophylactic, and (B) the curative treatment.

A. Of these, broadly considered, the Prophylactic Treatment is the more important. This is, however, a complex subject, involving questions too far-reaching to admit of discussion in the present communication. I venture, however, to make the practical suggestions which follow. The therapeutic use of narcotic drugs when necessary, should be guarded with every possible precaution. 1. The patient should, when practicable, be kept in ignorance of the character of the anodyne used and of the dose. 2. The physician should personally control, as far as possible, the use of such drugs and the frequency of their administration, taking care that the minimum amount capable of producing the desired effect is employed. 3. The occasional alternation of anodyne medicaments is desirable. 4. Sedative doses of narcotic drugs, and especially hypodermic injections of morphia, should not be used except in acute cases or in chronic painful illnesses likely to terminate fatally. The prolonged habitual administration of hypodermic injections of morphia is inadmissable, where recovery is to be hoped for. 5. The danger of yielding to the temptation to allow a merely palliative treatment to assume too great importance in the management of painful affections must be shunned. 6. An effort, which is too often likely to be unsuccessful, should be made to prevent renewals of the prescription without the direct sanction, or indeed without the written order, of the physician himself.

Too often these precautions are neglected, and the patient, betrayed by a dangerous knowledge of the drug and of the dose, and tempted by the facility with which the coveted narcotic may be obtained, falls an easy victim to habitual excesses. The lowered moral tone of convalescence from severe illness and of habitual invalidism increases these dangers. The uniform and efficient regulation of the sale of narcotic drugs by law would constitute an important prophylactic measure against habitual narcotism. Unfortunately, the existing laws relating to this subject are a dead letter; they are neither adequate to control the evil, nor is their enforcement practicable.

B. The Curative Treatment of the opium and morphine habit consists in the isolation of the patient and the progressive diminution of the dose. The method of Levinstein, which consists in the abrupt discontinuance of the drug, is cruel and hazardous; and is, so far as I am aware, neither advocated nor practised in this country.

The substitution of other narcotics is neither desirable nor necessary, except to meet special indications, and forms no necessary part of the plan of the gradual withdrawal.

Whether the treatment may be most satisfactorily carried out in an institution devoted to the care of nervous and insane patients or in a private house, is a matter of opinion. Certain it is that no confirmed case of the opium habit can be successfully treated under ordinary circumstances at his own home or if he is permitted to go about. The cases in which the home-treatment proves successful in curing addiction to opium or morphine must be looked upon as exceptional. The reasons for this are obvious. They relate to a variety of circumstances which tend to weaken the mutual relations of control and dependence between the physician and his patient. The doubts, criticisms, remonstrances, even the active interference, of the patient's friends tend to weaken the authority of the physician and to hamper him in the management of the case; the discipline of the sick-room is maintained with greater difficulty; the absolute seclusion of the attendant with his patient is a practical impossibility. Affectionate but foolish friends come with sympathy at once disturbing and dangerous. Some devoted servant cunningly conveys from time to time new supplies of the coveted drug, or, if these accidents be averted, the very consciousness of a separation which amounts to only a few feet of hall-way is in itself a source of distress to the patient and his friends alike. Furthermore, the period of convalescence following the treatment is attended with the greatest danger of relapse—a danger which is much increased by the facility of procuring narcotics enjoyed by the patient in his own home as contrasted with the difficulties attending it away from home under the care of a watchful attendant.

The desirability of undertaking the treatment away from the patient's home can therefore scarcely be questioned. That this plan is more expensive, and that it involves a radical derangement of the ordinary relations of the patient's life, are apparent rather than real objections to it. The very expense of the cure within the limits of the patient's ability to pay, and the mortification and annoyance of temporary absence from usual occupations and seclusion from

friends, are in themselves hardships that enhance the value of the cure when achieved, and constitute, to a certain extent, safeguards against relapse. Whether the treatment can be more advantageously carried out in an institution designed for the reception of several such cases, or in a private boarding house, is a question to be determined by circumstances. My own experience warrants the belief that these cases are best managed in suitably arranged apartments in private boarding houses, and by physicians, not necessarily specialists, but actively engaged in general clinical medicine. Under these circumstances the seclusion is more complete, and the patient is secured from even the chance contact of persons who may know him personally or by sight. It is not necessary that the proprietor of the house should know more than that he is a sufferer from some nervous ailment. Under this arrangement, many persons willingly leave home for treatment who could not under any circumstances be persuaded to enter a public or private institution for treatment; moreover, the control is more effectual and the personal relationship between the patient and his physician closer.

The symptoms which attend even the very gradual reduction of the dose are such as demand the most varied experience in clinical medicine and a wide range of therapeutic resources. They are familiar to you all; notwithstanding the utmost care in the management of the case, they are sometimes of dangerous severity.

The apartment occupied by the patient should be so arranged as to guard against attempts at suicide. The furniture should be of the simplest character; the heating and lighting arrangements must be such as to render any accident to the patient during paroxysms of sudden maniacal excitement quite impossible. From the beginning of the treatment the patient must under no circumstances be left alone. Two attendants are required, one for the day and one for the night. They should be not only skilful and experienced, but patient and firm, and as a considerable portion of the patients are persons of education and refinement, intelligence and good manners are desirable on the part of those who must be for a length of time not only the nurses, but also the companions of the sufferer. It is further desirable that the separation of the patient from his family and friends should be as complete as possible. During the continuance of the active treatment, no one should be admitted to the patient except his physician and regular attendants. So soon as the acute symptoms caused by the withdrawal of the drug subside and convalescence is fairly established, brief visits from judicious members of the family may be permitted in the presence of the nurse.

At the earliest possible moment open air exercise by walking or driving must be insisted upon, and change of scene, such as may be secured by short journeys or by visits to the sea-shore, is useful. These outings require the constant presence of a conscientious attendant.

Whatever may have been the form of self-administration of the drug, hypodermic injections of morphia should be chosen during the treatment by the physician. Three, sometimes four, doses should be administered in the course of each twenty-four hours. While the diminution should be in general terms progressive, it is desirable that the evening dose should be somewhat increased in amount in order to secure quietude during the night. The drug should in every instance be administered either by the physician himself or by a trustworthy medical assistant. This is a point of radical importance. It obviates all risk of excessive doses; it relieves the nurse from the importunities of the sufferer, which are always distressing and often intolerable; it keeps the patient in ignorance of the amount of the successive doses; and it establishes a degree of control and influence on the part of the physician which is of great advantage to all concerned. A large number of failures in treatment is due to the fact that the administration of the narcotic is entrusted to the care of the immediate attendants.

The rapidity with which the drug is withdrawn will be determined by the circumstances of the individual case. The time occupied is rarely less than a week, and not infrequently must be extended to a fortnight. If the administration of the morphia to correct urgent symptoms be at all required after this period, it will be at most on one or two occasions at intervals of twenty-four or forty-eight hours. When the process of reducing the dose is too gradually prolonged, the sufferings of the patient are unnecessarily aggravated. It is frequently desirable to continue the equivalent of the habitual dose for a few days after the isolation in order to investigate the peculiarities of the case and to establish the discipline of the sick-room. It is especially desirable during this period that the

patient shall take large amounts of easily digested and nutritious food, and it is a cardinal rule that throughout the treatment suitable nourishment should be systematically administered at short intervals and in full amounts.

The diet should consist of milk and lime water or Vichy water, peptonized or sterilized milk, Koumiss, Kéfir, concentrated broths, the expressed juice of fresh, slightly broiled beef, and the various commercial foods used in the artificial feeding of infants. The commercial peptonoids and especially Reed and Carnrick's liquid peptonoids, have been found useful.

Efforts to control vomiting by medicines other than the administration of opium and morphine in some way are not usually attended by success. Diarrhœa is best managed by the administration from time to time of large doses of bismuth subnitrate (gr. xx–xxx) every second, third, or fourth hour. The sinking feeling at the pit of the stomach and the epigastric pain are to some extent relieved by external applications. Hot fomentations or hot, wet compresses with a few drops of chloroform or turpentine are useful. For the relief of symptoms due to flagging action of the heart, the recumbent posture, external warmth, friction of the extremities, the application of turpentine or mustard to the precordial and epigastric regions, the inhalation of ammonia, or the administration of preparations of ammonia, will be required. Digitalis, strophanthus, sparteine sulphate, and adonidine are all useful. It is frequently desirable to begin the systematic administration of agents of this kind early in the case. Alcohol will, however, prove in the greater number of cases an indispensable remedy. It may be given in the form of milk punch, hot toddy, champagne, etc. Failure of the circulation may, notwithstanding every effort to control it, reach such a degree as to jeopardize the patient's life. Under such circumstances, the progressive diminution of the dose must be interrupted by the immediate administration of efficient doses of morphine, which, if necessary, must be repeated. As the tendency to diarrhœa increases, the quantity of urine excreted rapidly diminishes. It is often reduced to six or eight fluid ounces in the course of twenty-four hours, and after a few days of treatment it frequently contains albumin and occasionally casts. The oliguria is largely due to the excessive loss of fluid by the bowel, and does not require treatment. Nor is active treatment demanded by the albuminuria, which usually spontaneously ceases in the course of a few days. In the rare instances where it persists for weeks or months, appropriate treatment must be instituted.

The nervous symptoms are favorably influenced by methodical alimentation and the free use of alcoholics. Care must be taken to reduce the amount of alcohol administered as convalescence progresses. The danger of replacing a vicious habit of morphine taking by the more brutalizing vice of chronic alcoholism must be ever held in view.

It is hardly necessary to describe in detail the treatment demanded for the relief of the varied disturbances of the nervous system. The occasional use of cannabis indica, either in the form of the tincture or the extract, exerts a favorable influence. Neither the nitrites alone, nor nitroglycerine in combination with sparteine, as first recommended by Jennings, have proved useful in my experience. The ethereal extract of lupulin exerts a favorable but not very powerful influence in tranquilizing the nervous system. For twenty-four or forty-eight hours after the final discontinuance of morphine, but little effect may be expected from other sleep inducing drugs. Chloral in single large doses, either alone or associated with correspondingly large doses of the bromides, administered on the second or third night after total suppression, is often followed by prolonged, tranquil, and refreshing sleep. Paraldehyde, although a less certain, is a less dangerous hypnotic under such circumstances. Sulphonal, in doses ranging from 15 to 20 grains, is often a serviceable hypnotic during convalescence. Hyoscine hydrobromate may be used with advantage when there is great motor excitement. Massage, hot baths, and the cold pack are all useful adjuvants to the treatment.

The abject mental state of the patient calls for much firmness, gentleness, and tact on the part of the physician and attendants. Every effort should be made to inspire courage and hope. Neither the importance of the symptoms nor the intensity of the sufferings of the patient should be underrated; nevertheless, the ordeal is a limited one. In the majority of instances, to get rid of the opium means to get well, because opium, unlike alcohol, does not leave permanent structural lesions of any organ. The expectation of a radical cure must therefore be confidently presented to the patient as a consolation in his sufferings.

Insomnia and muscular weakness usually persist into the convalescence for some weeks, and only gradually yield to careful regulation of the daily life of the patient, with abundant nutritious food, open-air exercise, and change of scene. The insomnia of this period constitutes a serious symptom, for the reason that it constantly subjects the patient to the temptation to return to indulgence in narcotics. In the course of time, however, the normal physical and mental condition is regained, and the patient may be permitted to return to his former pursuits and associations.

The time occupied in the withdrawal of the narcotic and in the convalescence, constitutes on the part of the nervous system a period of gradual readjustment to normal conditions. Efforts to unduly shorten this period must in the nature of things be unsuccessful. The patient must therefore understand that his complete restoration to health demands a certain length of time. Any attempt to abridge this period by the substitution of other narcotics, exercising a less intense, or at all events, a modified effect upon the nervous system, are less likely to be permanently useful than the systematic employment of measures tending to improve to the fullest extent the general nutrition of the body and to bring about a wholesome moral sense and reasonable exercise of the will.

The curative treatment of habitual addiction to chloral is attended by neither the difficulties nor the dangers which are encountered in the management of the opium habit. The symptoms attending the discontinuance of chloral are less severe and less persistent; in fact, individuals accustomed to the taking of large doses of chloral not infrequently voluntarily discontinue its use for considerable periods of time. As a rule, the treatment may be carried out at home, the patient, however, being isolated and cared for by a watchful attendant. The drug should be stopped at once. For the first few days alcoholic stimulants should be freely given. Systematic feeding, pepsin, full doses of quinine, followed after a time by strychnia, and, as soon as the condition of the digestive system will permit of it, by iron, fulfil the general indications. Cod-liver oil and malt extracts may be given with advantage. Cardiac failure, collapse, and delirium tremens are to be treated in the same manner as similar complications occurring in the treatment of the opium habit. Vomiting is much less likely to occur, and when present is less persistent and less difficult of management. Diarrhœa does not usually prove troublesome, the bowels, on the contrary, being constipated. The latter condition yields to mild laxatives or to simple enemata. Hemorrhages from the various mucous tracts may be controlled by fluid extract of ergot, the hypodermic injection of solution of ergotin, minute doses of wine of ipecac, or fluid extract of hamamelis.

Two serious cases only of addiction to cocaine have come under my observation. In both of these the drug was at once stopped, with immediate relief from the epigastric and cardiac distress and the extreme bodily and mental depression which the habit had induced.

In conclusion, the following propositions may be affirmed:

1. No confirmed case of the opium habit can be satisfactorily treated at home. Suitable rooms in a private boarding house are available for a large proportion of the patients, including those who cannot be induced to enter a public or private institution.

2. Hypodermic injections of morphine, administered by the physician or by a medical assistant, constitute the best means of administering the drug during its gradual withdrawal.

3. The substitution of other narcotics, while occasionally required for special symptoms, does not constitute any necessary part of the treatment.

4. Many of the more serious symptoms following the withdrawal of the drug are prevented by the systematic administration of suitable food at short intervals and the judicious use of alcoholic stimulants.

5. The insomnia and asthenia of convalescence are incidental to the re-adjustment of the nervous system to normal conditions. So long as these symptoms persist, there is danger of early relapse and the patient should be kept under observation.

6. The convalescent must be warned that in the future the first dose of opium or morphia, either by the mouth or hypodermically, is likely to lead to the formation of the habit anew.

—Examinations in English schools go toward proving that color-blindness is frequently declared to be present when really no organic defect, but only poor training in the naming and distinction of colors, is found to be the trouble.

REPORT OF AMPUTATIONS PERFORMED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA FROM SEPTEMBER 30, 1874, TO DECEMBER 31, 1888.

BY LEWIS H. ADLER, JR., M.D.,
LATE RESIDENT PHYSICIAN, UNIVERSITY HOSPITAL.

The cases tabulated in the following paper comprise largely amputations done on account of railway accidents; which are always extremely dangerous, and are liable to be followed by bad results, even in subjects enjoying perfect health at the time of the accident, owing to the tendency to the development of mortification and pyemia.

Again, the results of the work of such men as Dr. D. Hayes Agnew, Dr. John Neill, and Dr. John Ashhurst, Jr., in a large institution such as the Hospital of the University of Pennsylvania, cannot but add somewhat to our knowledge of the mortality resulting from amputations.

The majority of these operations were done before the present strict antiseptic treatment came into vogue, and it is certain that the statistics of the future will make a better showing. But still, the care and personal attention of the Surgeon-in-chief, which have always characterized the treatment of such cases in this Hospital, both during the operation itself and during the period following it, are important factors in the reduction of the mortality from this operation.

I have followed in the arrangement of the statistics in this paper the plan adopted in similar papers, by both Dr. George W. Norris,[1] and Dr. Thomas G. Morton,[2] surgeons to the Pennsylvania Hospital, in their published reports of the statistics of amputation.

In the tables sub-joined, all amputations in which the operation was performed within twenty-four hours subsequent to the accident are included under the head of Primary. The other divisions—Secondary and Chronic—explain themselves.

Of 290 patients upon whom 320 amputations were performed during a period of a little over fourteen years—(extending from the opening of the hospital, in 1874, to 1889 inclusive) 73 died, or 25.1 per cent.

Of this number 21 were primary double amputations; 3 primary triple amputations; 1 secondary double amputation, and 2 were double amputations for chronic trouble.

Of the 21 primary double amputations 11 patients recovered; 10 died, or 47.6 per cent.

Of the three primary triple amputations 2 patients died, or 66⅔ per cent.

The case of secondary double amputation recovered.

Of the cases of secondary amputations for chronic trouble, all the patients recovered.

TABLES OF DOUBLE AND TRIPLE AMPUTATIONS.

Double amputations:		*Result.*	*Age.*

upper extremity; of this number 10 patients died, or 10 per cent.

163 of the amputations were of the lower extremity; of this number 52 patients died, or 31.9 per cent.

In one of Dr. Geo. W. Norris's papers upon amputations,[1] previously referred to, mention is made of the mortality of such operations in the following terms:—"In a large hospital no operation is more frequently called for than that of amputation, and even where the time for doing it is judiciously determined, and the operation itself dexterously and well performed, the dangers to which the patient is afterward exposed, are so great as to render the subject worthy of all attention from the practical surgeon. Contrary to the opinion generally prevalent in this country, amputation, even under favorable circumstances, is very frequently followed by fatal results in civil hospitals. In the practice of the Hôtel Dieu, of Paris, it is said that not more than half of the cases prove successful,[2] and I have the authority of M. Hache, a former interne of the hospital of St. Louis, of the same city, for stating, that out of twenty

15	ankle-joint & foot "	1	" 6⅔

100 of the above amputations were of the

successive amputations made in the year 1833, in that institution, twelve died, or 60 per cent. With one exception (that of a toe) all these were capital amputations, and at the time the statement was made some of the patients were remaining still uncured."

When we recall the fact, which is often overlooked in the comparisons of older statistics with those of the present day, that anæsthetics have only been used to relieve

[1] *American Journal of Medical Sciences*, August, 1838.

[2] *Gazette des Hôpitaux*, 1834.

suffering in these capital operations for a little over 40 years, and that the additional suffering inflicted before their use added largely to the shock and consequent mortality of this operation—we must, in summing up our conclusions as to the more favorable results obtained now, give credit to anæsthetics as important factors.

Again, the facilities for handling cases requiring amputation are greater now; the perfection of the railway system permits of the early inspection of the patients by the surgeon; and the accommodations offered to patients recently injured in the numerous hospitals scattered over the land, where with careful nursing and the constant presence of the house-surgeon, dangers can be met and guarded against—all tend to lessen the mortality of amputations.

From this *résumé* of amputations performed in a little over 14 years at the University Hospital, it appears—

1. That amputations of the lower extremity are more liable to prove fatal than those of the upper extremity. (Norris.)

2. That the rate of mortality is greater in proportion to the proximity to the trunk of the part amputated.[1]

3. That, contrary to the statements usually made in other published statistics, the mortality of amputations for chronic disease is about the same as for recent injury—the former being 23.75 per cent., the latter 23.5 per cent. The explanation of this may be found in the fact that many of the cases were operated upon for chronic disease of a malignant character — sarcoma; etc.

4. That the danger increases with the age of the individual operated upon—a point previously brought forth in the investigations of Dr. Norris.[2]

5. That in double synchronous amputations the prognosis is very favorable when the patient is under 30. Above that age the mortality is at least 75 per cent.—one chance in four in favor of recovery.

41 North Twelfth Street.

—The Charité, the largest medical institution in Berlin, is to be enlarged. In order to provide more space for beds, room for lecture halls will be provided in separate buildings, and the space thus gained will be used for patients. The same thing will be done with the out-patient rooms.

ANCHYLOSIS OF LARYNGEAL ARTICULATIONS FROM CANCEROUS INFILTRATION. RELIEF BY INTUBATION.

BY JOHN J. REID, M.D.,
NEW YORK CITY.
SURGEON TO CHARITY HOSPITAL.

The following case is of interest in several respects. First, as to the cause of the dyspnœa; second, with regard to the impossibility of making a correct diagnosis, even if the operation of extirpation of the growth had been performed; and finally, because of the benefit derived from intubation whilst the case was under consideration.

The history is briefly as follows: The patient, a widow 70 years old, entered the Charity Hospital, giving a history of hemiplegia coming on six weeks previously. Subsequently a growth was noticed about the middle of the neck, and to the left of the median line. Hoarseness followed, which was succeeded by dyspnœa of a spasmodic character. This growth was soft and fluctuating, but when the needle was inserted, no fluid was obtained. The diagnosis rested between cancer of the thyroid gland and abscess. The rapid development and fluctuating character of the tumor favored the latter view, but the nodular feeling, together with its connection with the thyroid, strengthened the suspicion of carcinoma. The most important question was as to the connection of the growth with the dyspnœa, and the necessity of immediate operation inasmuch as the most rational supposition was that pressure of the mass from behind obstructed the calibre of the trachea.

While the case was under consideration an O'Dwyer tube was inserted. This relieved the breathing and lessened the urgency of operative interference. Within thirty-six hours the patient died of exhaustion.

Autopsy.—The mass proved to be a cancerous growth of the thyroid, which extended upward along the trachea, but did not obstruct its calibre. At its upper part it invaded the posterior wall of the larynx, but did not project into it. The vocal cords were perfectly rigid, and would permit only the tip of the little finger to enter the chink of the glottis.

It was evident from an examination of the specimen that the dyspnœa was not due to the mechanical effect of the growth, but to the infiltration of the larynx, which caused anchylosis of the articulations and resulting stenosis.

SOCIETY REPORTS.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, April 22, 1889.

The President, ALEXANDER S. HUNTER, M.D., in the Chair.

Dr. G. H. Fox read a paper on the

Treatment of Acne Without Arsenic, Sulphur Ointments, or Lotions,

and said that it was not to be inferred from the title that he objected to the use of arsenic, sulphur ointments, or lotions; he simply believes their field of usefulness to be limited. On the average, it is probable arsenic does more harm than good in these affections, because it is administered without discrimination.

He divided acne, for convenience in treatment, into two forms, the irritable and the indolent. In the irritable form the skin is usually fine and soft, quickly inflamed by applications, and admits of no other than the most soothing treatment. This form of the disease is largely of a reflex nature, due especially to disorders of digestion and of the sexual organs. It is chiefly benefited by diet and internal remedies. The indolent form shows usually a coarse, doughy, often greasy skin. In these cases the glands, which are the seat of comedones and pustules, should be evacuated; in other words, the skin should be kept clean; soap and water, ointments and lotions are not sufficient.

Most physicians place much reliance upon arsenic as an internal remedy in acne, but on the whole it is probable that patients would get along better if it were unknown. Sulphide of calcium has been recommended highly, but is likely to lead the physician to neglect more important measures. Ergot possesses greater value than is generally attributed to it, its chief benefit being achieved in the indolent form. In irritable acne Dr. Fox now seldom uses the many internal remedies with which he has formerly experimented. The chief principles of treatment to be followed in acne, are the regulation of the diet and the use of local massage. Massage can be applied by squeezing out the comedones, emptying the pustules, and scraping with the round curette, kneading with the fingers, etc. But no fixed plan of treatment can be laid down for all cases.

DR. L. D. BULKLEY then read a paper on a

Clinical Study and Analysis of Cases of Psoriasis and their Treatment,

which was a review of twenty years' experience with the affection. The disease, being one of the most common and persistent of skin affections, deserves careful study. It rarely attacks the skin of the palms of the hands or soles of the feet. Dr. Bulkley has not seen it on the tongue. It formed over 4.3 per cent. of all the cases of skin disease which had come under his observation. According to statistics, it seems possible that changes in temperature with much moisture has something to do with its causation. He has treated 264 cases altogether. His statistics harmonize in most respects with those of general collections. He has found that between ten and fifteen years of age the female patients were double the number of male patients. While between fifteen and twenty-five years of age the males were double the females. Over forty per cent. of all cases appear before the second decade of life. The youngest patient seen by Dr. Bulkley was a little over a year old. Over one-third of all his cases had lasted over ten years, and some as long as forty or fifty years. Many patients ceased their visits long before the eruption disappeared. Over forty per cent. of his cases remained under observation less than six months; quite a proportion of these, however, yielded to treatment, and were apparently cured. As the disease advances in duration, a smaller proportion is benefited. But sometimes careful and continuous treatment will keep the eruption almost entirely in check even a great number of years.

The disease has scarcely any tendency to self-limitation. Although its virulence is largely due to the patient's carelessness, yet there are cases which prove intractable however carefully the treatment may be carried out. It is most curable in children. The cases in patients between the twentieth and twenty-fifth years of age are very rebellious. The treatment should include diet, general hygiene, medicinal measures, the bath, internal and external medication.

Psoriasis is not a local disease, but a constitutional one, more or less akin to rheumatism and gout. Excessive meat-eating increases its severity, and the use of stimulants precipitate an attack. Oils and fatty matter, if properly digested, favor a cure. Pure wool should be worn next the skin, and sudden changes of temperature avoided.

Patients get along better in a warm, equable climate. As regards internal medication, arsenic undoubtedly causes the eruption to disappear in some cases. He had one patient who had taken, it was estimated, a gallon of pure Fowler's solution within fourteen years. Alkalies are also beneficial. Local applications may prevent in a large degree development of the eruption, if they are applied early. He has about abandoned chrysophanic acid in private practice. He has used more of white precipitate ointment in various degrees of strength than of any other local application. Mineral waters seem to have little influence on the disease. Among them sulphur waters hold the best place.

The papers of Drs. Fox and Bulkley were discussed at considerable length by Drs. R. W. Taylor, H. G. Piffard, C. W. Allen, E. B. Bronson, Sherwell, William H. Thompson, Cranmer. In general they agreed with the authors. Drs. Piffard and Allen value sulphide of calcium in acne, and also chrysarobin in psoriasis, and so does Dr. Sherwell. Drs Bronson, Sherwell, Piffard and Cranmer, laid stress on disturbance of the sexual system as a factor in the production or aggravation of acne, and all considered massage and evacuation of the pustules important. Dr. Taylor and some others referred to the probable influence of a microbe in some cases of acne. Dr. Fox in closing the discussion said that in writing his paper he had sought to present what was true rather than what was new.

—The *Quarterly Jour. of Inebriety*, April, 1889, says that the Vienna School Board have for some time past made laudable but ineffectual efforts to prevent the sale of strong drinks to children. They have just passed a resolution to appeal for government intervention, and it is proposed to lay before Parliament during the present session a bill for prohibiting the sale of intoxicating liquors to boys and girls under fifteen years of age. As a matter of fact, inebriety among Austrian school children is not uncommon, and the little boy that appears in the class-room in a state of intoxication has ceased to be a phenomenon. During the winter months the children of the poor are often sent off to school on empty stomachs, and in many cases a glass of the very cheapest spirits is given to them to keep out the cold. Amongst the Slav portion of the population, urchins of five and six often take a liberal dose of alcoholic drink on their way to school, without apparently being the worse for it.

Reports of Clinics.

UNIVERSITY HOSPITAL.

SURGICAL CLINIC—PROF. AGNEW.

Commencing Arthritis.

Dr. Agnew showed to the class, on March 13, a boy about ten years old who had a commencing arthritis of the right ankle-joint. There was a slight amount of swelling on the internal side of the ankle, indicating the commencement of an arthritis. Dr. Agnew said it would be possible to abort this inflammation, by introducing around it a few turns of a roller bandage of plaster. This must be renewed in a few weeks, when, as the swelling went down, the first bandage would become loose. In the meantime the child should be kept in bed or on crutches, with the limb in an extended position, alterative tonics being administered and the general constitution carefully looked after.

Removal of a Cancerous Breast.

The next patient before the class was a woman, forty-five years old, who had a tumor of the left breast which began about eighteen months ago. It was now very painful and hard. The skin was adherent over the tumor and the nipple was decidedly retracted. Dr. Agnew regarded the growth as cancerous, and removed the breast, taking especial care, at the same time, to take out the neighboring glands, which had also become involved and which, when left after an operation, are either a cause of the return of the tumor or, at least, of its returning more quickly than it would otherwise do from the mere cancerous diathesis alone. Dr. White then closed the wound with an antiseptic iodoform dressing, having introduced a drainage tube. This dressing is allowed to remain on twenty-four hours. The tumor removed weighed two pounds, notwithstanding its small size, thus exhibiting the characteristics of this class of growths in having great weight in proportion to their size. It was already commencing to undergo degenerative change in the centre.

Multiple Exostoses.

The first patient showed to the class on March 20, was a woman twenty-one years old. Some time ago she had had removed an enormous exostosis from the posterior part of the thigh. She recovered satisfactorily from the effects of the operation;

but the diathesis still continues, she having at present one hundred and twenty-seven bony prominences in different parts of the body. When these exostoses cause pain or spasm by pressing upon a nerve, or when by their mere position or size interfere with the action of muscles or tendons, they have to be removed. The one removed at this time was situated on the right leg, say an inch below the knee, and a little to the left of the median line, so that it slightly interfered with the action of the tendon of the quadriceps extensor. Upon cutting down to the bone the tumor was found to originate from three prominences, each of which had to be removed. The mallet and chisel were first used and then the forceps. The exostosis had also to be taken off where the tendon of the sartorius runs.

On the outside of the leg, but rather higher and farther back, another prominence had to be removed, because it interfered with the action of the insertion of the tendon of the biceps. Here more care had to be taken on account of the presence of the popliteal nerve. When the operations were completed, drainage tubes were introduced and the wounds closed with the usual antiseptic precautions, additional care being taken to have the joint bandaged in an extended position upon a splint covered with raw cotton, to guard against the possibility of healing taking place with the limb in a flexed position.

Removal of the Great Toe and its Metatarsal Bone for Necrosis.

It is always difficult on the foot to determine the extent of necrosis from the external appearances of the soft parts; because an apparently insignificant sinus may open down to many necrosed bones. This arises especially from the fact that the synovial membranes opened are large and open into one another, so that a large surface of synovial membrane may be brought in contact with the air; and, moreover, when the synovitis is once established, an arthritis is especially apt to follow, owing to the bones being so close together.

This man is forty years old, and his present trouble began three years ago without an injury. Let this fact serve to impress upon you the importance of early opening of abscesses on the foot, owing to the tendency of the pus to burrow and establish sinuses, because it is bound down by dense fasciæ. So, too, with an abscess in the ischio-rectal fossa, which, unless opened, will cause an incomplete internal fistula in ano.

After the patient had been etherized and the Esmarch bandage had been applied, the right foot over the internal metatarsal bone and even closer to the ankle was found riddled with sinuses, and upon cutting down along the internal metatarsal bone, it was found necessary to remove not only the latter, but also the cuneiform bone and the great toe. The bottom of the wound was then curetted by Dr. White, any exuberant granulation tissue being thus removed from the neighboring bones. Dr. White then introduced a drainage tube and dressed the wound antiseptically, leaving the foot in a very good condition for future usefulness.

PERISCOPE.

The Hughes Crematory.

The city of Savannah, Georgia, says *Science*, April 12, 1889, is soon to have a crematory for the destruction of garbage by fire. The model selected is that known as the Hughes Crematory, and is thus described by the *Savannah News:*

The crematory will be about 30 feet long, and from 15 to 20 feet wide. The main body of the kiln or furnace is a vertical shaft built of brick. At its base will be two hydrocarbon-burners. Upper and lower triangular flues extend across the middle of the shaft, and also an upper and lower set of baffles or side-wings, which are connected by means of wall passages or flues. Underneath these is a shelf, forming a retort in which air may mix with the flames from the burners. Flues are provided for the return of the gases arising from the incineration to a smoke-stack at the side of the shaft. A hydrocarbon-burner is placed at the bottom of the shaft conveying the gases to the chimney, which deodorizes them before they pass out into the air. Perforated steam-pipes are located over the top drop-shelf of the shaft, connecting the burner with the boiler, so that the fluids may be carried off.

The operation of the crematory is simple. When the furnace is brought to the required degree of heat, a load of the material to be burned is emptied into the top of the shaft. It falls on the first drop-shelf. After a suitable period this shelf is dropped, and the mass of material is allowed to fall on the second shelf, and a second is dumped into the kiln. After another interval the second drop-grate is allowed to fall, and the material is thrown upon the baffles and flues below, whence the residuum finally drops down into the ash-pit at the bottom of the

shaft. The capacity of the crematory will be 50 tons of garbage per day, and the cost of the process is from 18 to 20 cents per ton.

In Montreal it costs just $43,000 to destroy by fire a year's miscellaneous refuse, and $8,000 additional for the burning of its night-soil. The destruction of the latter costs 75 cents per ton, and of the former 25 cents per ton. In Minneapolis it is estimated that 15 to 20 cents per ton of refuse pays for the labor employed and the fuel used. Within five days recently the refuse cremated consisted of 33 horses, 59 hogs, 103 barrels of hotel and commission-house refuse, 12 loads of market offal, and 70 loads of manure. The aggregate weight was 200 tons, but the ashes deposited in the course of consumption weighed considerably less than 1,000 pounds. The total cost of labor and fuel for this five days' period was $38.25.

On the Action of Antipyretics.

Aronsohn, Sachs, Richet and, later on, Girard in 1885, experimentally demonstrated the existence of a special thermic centre, situated in the striate body. Soon afterward, Zavadovsky and Vladimïr I. Podanovsky drew attention to the fact that the antipyretic effects of antipyrin and antifebrin are determined solely by their action on the cerebral thermic centre, any direct influence on tissues (their chemistry, blood-supply, etc.) being out of the question. Quite recently, Dr. Podanovsky and Professor Sergëi A. Popoff, of St. Petersburg, have carried out a long series of experiments on lower animals with the view of studying the mode of action of other antipyretics, such as quinine, resorcin, and thallin (*Proceedings of the Third General Meeting of Russian Medical Men at St. Petersburg*, No. 9, 1889, p. 283). In rough outlines, the authors made a division of the brain just behind the striate body, and then introduced into the animal this or that antipyretic drug. The main outcome of their important researches may be given as follows: 1. The division of the brain behind the striate body is immediately followed by a steadily increasing and permanent fall of the central systemic temperature. A subsequent introduction of even most powerful pyrogenic (septic) substances does not produce the slightest impression on the temperature, though it gives rise to other usual symptoms of septicæmia, such as initial fall and subsequent rise of the arterial tension, acceleration of breathing, cardiac action, diarrhœa, etc. 2. The facts can be explained only by the admission, first, that there exists a special cerebral centre, capable of responding to a septic poisoning by an elevation of the systemic temperature; second, that the operation isolates the centre from the rest of the body; and third, that systemic tissues of themselves are powerless to bring about any rise of the body temperature. 3. In such animals, antipyretics—antipyrin, antifebrin, thallin, etc.—are similarly unable to cause any change in the central temperature. 4. Neither can they alter the peripheral (cutaneous) temperature, notwithstanding the fact that both irritability of the vasomotor centre in the medulla oblongata, and contractility of the cutaneous blood vessels remain quite normal. Meanwhile, in normal—*i. e.*, animals non-operated upon—the introduction of the antipyretics gives rise to a rapid and considerable increase of the peripheral temperature. 5. Generally, there does not exist any strict parallelism between the antipyretic action of the drugs and their property of elevating the cutaneous temperature. 6. All antipyretics act on the central and peripheral temperature in healthy animals by far less markedly than they do on that of febrile ones. 7. The antipyretic effects of the drugs are undoubtedly dependent upon their specific action on the cerebral thermic centre. 8. In the beginning, the action is exciting, but subsequently it is sedative. 9. The facts adduced under "4" point out that, beside a medullary vasomotor centre, there exists a special higher one, situated in the anterior lobes of the brain. It appears to be designed for increasing the systemic heat-loss in cases in which there arises an excessive heat-formation.

Impotence Consequent on Varicocele.

Segoud reports on a case brought forward by M. Jamain in which the radical cure of a varicocele was followed by return of sexual power in a man 26 years old, in whom it had been in abeyance since puberty. This "frigidity" had resisted all methods of treatment, but ceased when the patient lay on his back. This position, or the use of a suspensory bandage, reducing the varicocele, caused an erection. Potency was readily brought about two months after resection of the spermatic veins. The author quotes various similar cases, especially one by Vidal de Cassis, in which the impotence and puerile voice peculiar to castrated persons disappeared after the operation.—*London Medical Recorder*, April, 1889.

Salicylic Acid in Chronic Tuberculous Joint Disease.

In the *Boston Med. and Surg. Journal*, April 11, 1889, Dr. Robert W. Lovett recommends salicylic acid in the treatment of chronic tuberculous joint disease, and cites cases illustrating its usefulness in subduing the pain, and especially in controlling the spasmodic pains so commonly manifested by "night cries." He states that in the cases coming under his observation no mishaps have occurred in the use of the drug, although in cases in which it was continued for a long time the kidneys were watched to see that no nephritis was set up; in hospital out-patients the drug was not ordered in cases in which the parents were not careful, and able to bring the child each week to the clinic. The salicylic acid was prescribed in the form of the salicylate of soda, made up in five-grain tablets; these were taken readily, without complaint. The experience in the use of the drug in this connection has led of late to its wider and earlier use in the hospital clinic, always, however, he is careful to say, as an adjunct to proper mechanical treatment.

His conclusions are: That salicylic acid in large doses is useful as an aid to the mechanical treatment of chronic tuberculous joint disease, not in routine conditions, but (1) when night cries are present; (2) when the diseased joint is very painful and sensitive to jar; (3) when vomiting and general discomfort are associated with an increase in the local disease.

Relief from pain and the diminished sensitiveness, he says, follow at once, as quickly as in acute articular rheumatism. He recommends that the drug should be given in as large doses as for articular rheumatism, until the pain is relieved or the physiological effect is produced.

Splenic Murmurs.

In a paper read before the Clinical Society of Paris (*La France Médicale*, No. 36) Prof. Bouchard drew attention to the existence of a bruit over the region of the spleen in cases of enlargement of this organ—a bruit not attributable to pressure upon vessels or to conduction from the heart, but apparently generated in the splenic artery or in the spleen itself. During the past three years he has constantly practised auscultation of the spleen, and on five occasions has detected such a bruit. Three times the splenic enlargement was due to cirrhosis of the liver; in one case the spleen was hypertrophied, as in leukæmia, but the blood was not altered; and in the other the swollen spleen was associated with a large liver in an obese subject. In several cases—notably in malarial spleen and in one marked case of leukæmia—no bruit was to be detected. He entered into details of his first case—one of cirrhosis of the liver,—in which the spleen was very large, measuring seventeen by eleven centimeters (about 6.3 by 3.9 inches) and was hard and smooth. Over its whole area there was audible a soft prolonged bruit synchronous with the pulse, but the bruit could not be traced beyond the splenic region. It was still audible when the patient was made to lie on the left side, to prevent the organ exercising any pressure upon the abdominal vessels. The bruit was audible whenever the patient was examined during the three years the patient was under observation. The case was otherwise interesting as an example of "cured cirrhosis," upon which the chief discussion took place. There had been considerable ascites, which required paracentesis on three occasions; but Prof. Bouchard attributed the arrest of the disease to the prolonged administration of calomel in small doses. The patient also had an attack of uræmia, which was successfully treated by naphthol, on the theory of intestinal antisepsis being needed to limit the operation of auto-intoxication in the production of the uræmia.—*Lancet*, April 6, 1889.

Infectiousness of Croupous Pneumonia.

Dr. N. I. Sokoloff lays down (*Transactions of the Third General Meeting of Russian Medical Men at St. Petersburg*, 1889, p. 384) the following propositions, based on researches of his own: 1. Croupous pneumonia is an infectious disease. 2. Typhoid fever patients are especially liable to be infected with the pneumonic virus. 3. The mortality amongst typhoid fever patients contracting pneumonia is truly enormous; in fact, it amounts, on an average, to 66 per cent. 4. In view of this fact, every hospital must be furnished with special wards for cases of pneumonia. 5. When pneumonia makes its appearance amongst hospital typhoid fever patients, the latter must be at once isolated, and the wards concerned must be disinfected most thoroughly. 6. The pneumonia wards must be similarly disinfected before they are used for patients suffering from other affections. 7. In view of a considerable general mortality from croupous pneumonia—which, even with the best possible management, proves to be as

high as 12 per cent.—as well as in view of the intense infectiousness of the disease, the strictest sanitary precautions should be adopted as soon as a pneumonia epidemic breaks out at a given locality.

Tapping and Irrigation of the Ventricles.

At the meeting of the Philadelphia County Medical Society, Feb. 13, 1889, Dr. W. W. Keen read a preliminary report on a case of tapping and irrigation of the ventricles of the brain, and said: Last fall I made a proposition for tapping the lateral ventricles. At that time I was not aware that the procedure had ever before been suggested, but I have recently learned that, in 1881, Wernicke suggested it in a general way, and by the lateral route. I, however, first formulated definite rules, which have stood the test of actual trial. The operation, I believe, was never performed until I did it in a case of marked choked disc on both sides, with complete blindness dating from last Christmas, which I had the opportunity of seeing through the politeness of Dr. Strawbridge. I tapped the ventricle five weeks ago last Friday, reaching it by the lateral route, at a depth of one and three-fourths inches from the dura mater. A half-inch trephine opening was made, a crucial incision in the scalp and dura being employed, as I intended to keep up drainage. From two to four ounces of cerebro-spinal fluid escape from this opening daily.

The case was examined from day to day to see the effect on the swelling of the optic discs. Before the operation this amounted in one eye to 2.3 mm., and in the other to 1.8 mm. After the operation, it eventually fell to 0.83 mm. on each side. At the end of a week the horse-hair drain, which was introduced at the time of the operation, was substituted by a rubber drainage tube passing into the ventricle. The discharge then became freer, amounting to four to eight ounces per diem.

In addition to this, I explored with a probe the occipital lobe on the left side, twice to a depth of three and a half inches, but found no tumor. I then made a small opening by a gouge under the cerebellum on the left side, and explored the left lobe; and then passed obliquely into the right side, but no tumor was found.

Last Friday I trephined the child on the opposite side, thinking that there might be a tumor in the posterior lobe on that side, but I found none, though I touched the tentorium and the falx. I then tapped the lateral ventricle on that side. Yesterday I washed out the lateral ventricles, passing about eight ounces of a solution of boracic acid (four grains to the ounce) from one side to the other. There was some little irritation resulting from the manipulations, but the moment the warm solution began to pass through the ventricles the child settled itself into a position of complete comfort.

I will pass around a bottle of the cerebro-spinal fluid, which has been standing on my desk for a week. There are no signs of decomposition. The fluid contains both sugar and albumin. This with its continuous flow, proves it to be cerebro-spinal fluid.

The child did not suffer any notable rise of temperature after any of the operations, with the exception of the last one. Then there was a temporary sharp rise to 104°.

Acute Localized Œdema.

At the meeting of the Glasgow Pathological and Clinical Society, February 25, Dr. Napier described a case of acute localized œdema. The patient was not presented, as his eruption had in the meantime disappeared; he was a strong, healthy-looking young man, 24 years old, whose illness had begun a year ago. In his early years he had masturbated frequently, but had suffered nothing apparently from the practice. About a year ago, he fell in with some quack literature of the ordinary kind, the study of which completely upset him mentally; he became "nervous," unable to keep his attention fixed on anything for any length of time, restless, and hypochondriac, and had to give up work for a considerable period. About three months ago, the swellings he complains of were first noticed. They are generally preceded by a sensation of irritation and heat, sometimes by no abnormal sensation at all; in an hour or two the part swells, forming elevations two to four inches long, and about two inches broad, tense, shining, hot, and tingling, and not pitting on pressure. In six or eight hours the swelling disappears, leaving no trace behind it. The affection has appeared in nearly every part of the body, chiefly on the face, limbs, and chest; several times it has occurred on the penis, tongue, and throat. Dr. Napier compared this case with a series of cases in which rapid swelling of face and hands had followed exposure to cold on emerging from a very warm atmosphere, the patients having been moulders and hammermen.—*Glasgow Medical Journal*, April, 1889.

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Physician's Daily Pocket Record, - - - 1.00
Reporter and Pocket Record, - - - - 6.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE PHILADELPHIA HOSPITAL AND THE MAYOR.

One of the positions held by the late Dr. Edward T. Bruen was that of Attending Physician to the Philadelphia Hospital. His death created a vacancy in the Medical Staff of that important institution, and this gave rise—as every vacancy there does—to an active canvass for the place. The usual effort was made by a number of worthy candidates to secure the endorsement of the surviving members of the Staff which, under the Civil Service Rules in force in this city, is the prerequisite of election by the Board of Charities and Correction.

While this was going on, another candidate, was put forward by the Mayor of the City, who first endeavored to have him appointed without reference to the wish of the Medical Staff, and, when told that its nomination was indispensable to an election, instructed the President of the Board of Charities and Correction—Dr. James W. White—to order the Staff to nominate him.

After expostulating in vain with the Mayor, Dr. White transmitted this order. The Medical Staff of the Hospital then met and nominated three candidates for the vacancy, but passed the Mayor's candidate by—he receiving only one vote out of seventy-eight cast by twenty-six voters, each voting for three candidates.

Thereupon the Mayor asked Dr. White, who has been a most faithful and efficient public officer, to resign; and when this request was refused he issued an order that he be dismissed, and appointed a new member of the Board and a new President.

Our readers who have followed the story thus far will not be surprised to hear that this conduct of the Mayor has brought upon him scathing rebukes from almost every newspaper in Philadelphia, and that he stands before the citizens as a man set to enforce the law who has deliberately attempted to break one of its most salutory provisions. This is an aspect of the case which concerns every citizen, and the physicians of Philadelphia need not trouble themselves especially to condemn it, for the whole city has taken the matter up and will probably make its sentiment understood and, in time, respected.

But there is another aspect of the matter which concerns medical men more than others. This aspect relates, not to the Mayor but to the Medical Staff of the Hospital and to the candidate of the Mayor. The Medical Staff deserves the support and praise of all men who admire honor and courage. Its members were threatened with the hostility of the Mayor if they did not name a man to share their duties and responsibilities who was regarded as fit for the position—as the vote indicated—by only one out of twenty-six physicians, surgeons and

accoucheurs who voted, and who can be assumed on general principles to know more about his character and ability than the Mayor, who says he has never seen him.

On the other hand the Mayor—censurable as he is—is not the only person to be censured. Those who persuaded him to his false step deserve censure also. The representatives of a medical school which has failed to secure the respect of the most intelligent and conscientious members of the medical profession in Philadelphia, and which has been so conducted that this last step is no surprise to those who have watched it carefully, have attempted, by posing as martyrs and by appealing to the autocratic part of the Mayor's nature, to secure what they could not get in the way open to those who have real merit.

In doing this they have forfeited any claim which they might think they had on the score of equal representation, and have justified the suspicion and disapproval which have heretofore stood between them and positions of honor in the medical profession of Philadelphia. They ought to know—and if they are not lost to reason they will yet learn—that integrity and ability are essential to gaining the approbation of their fellows in the medical profession, and that no success in persuading mere politicians is a desirable substitute for such approbation.

If this lesson is made prominent by the unhappy occurrence described above, it will not be without its uses, and good may yet come of what is in most respects a very shameful piece of business.

THE SACRO-COCCYGEAL ROUTE FOR INTRA-PELVIC OPERATIONS.

In the REPORTER of April 27 attention was called to the method of operation on the rectum which includes a temporary resection of the coccyx and a part of the sacrum, with division of the sacro-sciatic ligaments. It may be interesting, in connection with this, to advert to the fact that more than one surgeon has entertained the idea that the route to the cavity of the pelvis which can be made in this way might be utilized for the removal of various morbid products in the pelvis of women. Hochenegg and Herzfeld, last year, recommended this for total extirpation of the uterus, and tested the operation on the cadaver. The proposition has met, we believe, with approval from Hegar, and more recently—in the *Berliner klinische Wochenschrift*, March 11, 1889—by Dr. W. Wiedow, of Freiburg, who has discussed its value in regard to operating for pelvic abscesses, and diseases of the ovaries and Fallopian tubes, as well as for removal of the uterus.

In his paper Wiedow gives an account of three cases in which he adopted this method: once for a pelvic abscess; once for extirpation of a cancerous uterus; and once for the removal of diseased tubes. As a result of his experience and reflection, he concludes that the method referred to is of value in operations for pelvic abscess, and that it is preferable to vaginal hysterectomy. For operations on the Fallopian tubes he thinks it is not better than laparotomy.

These conclusions seem to be justified by what Wiedow reports of his cases, and they appear to be reasonable on general anatomical and pathological grounds. Certainly no one could ask a better method for operations upon the Fallopian tubes than that of Tait, which is practised so often and so successfully in this country, and especially in this city. We think the same may be said of the usual operation for what is called pelvic abscess; and that it is hardly likely that American surgeons will choose a route which involves a resection of the sacrum and division of the sacro-sciatic ligaments, when the route through the abdominal wall serves so well as it does nowadays.

But the case is different in regard to operations for removal of the uterus. Hysterectomy is, we believe, generally done through the vagina at present. It is often a very difficult and sometimes—as in two cases which the writer of this has witnessed—

a formidable operation. The greatest difficulty it presents depends upon the fact that its most delicate steps are conducted in the dark. The method of Kraske, or that of Levy, permits of bringing the field of operation into view, and eliminating the danger of wounding or ligating portions of the intestine. This is a theoretical advantage which will not be despised by those who have confronted the difficulties of vaginal hysterectomy.

Experience alone can determine whether, or not, the technical details of operation through the sacro-coccygeal region are so great as to outweigh the advantages it offers; but this method is certainly worthy of consideration. It may be that it will fulfil the expectations of those who propose it, and if so the field of its usefulness will doubtless widen in directions which have not yet been suggested. For example, it is among the possibilities that this method may, in some cases, supplant the Cæsarean section, and afford at the same time a means of radically curing defects which prevent normal parturition. This is a matter to which we invite the attention of our readers who practise largely in the field of operative obstetrics, in the hope that their judgment and experience may lead to a determination of the true value of this suggestion.

THE ADVANCE OF MEDICINE IN JAPAN.

History presents no parallel to the advance of the Japanese people during the past fifty years. Scarcely a half century ago anything foreign was looked upon with superstition and dread, and foreigners were distrusted and shunned. The country was in a barbaric state. Today Japan has schools rivalling those of Europe or America; a complete postal and telegraph system; a standing army, thoroughly drilled and armed with the most approved of modern weapons; a navy which ranks with those of European countries; a police force of strength and efficiency in every city and town; railroads traversing the country from end to end and fast increasing; reliable banks, thriving news-papers, a people's government, and lastly a University where the best talent of Europe and America is represented in the corps of instructors, and where degrees in law, science, physics, chemistry, philosophy, philology, civil engineering, medicine and dentistry may be obtained.

In the beginning of the sixteenth century Japan was fast becoming a Christian country. The Dutch traders were greatly liked by the *Shogun*, or ruling power, and foreign introductions were encouraged. More than this, Christianity was looked upon with favor, and the Jesuit missionaries found no opposition. This happy state of affairs continued for nearly a century. The Christians in the southern part of Japan numbered several hundreds of thousands; but at last the powers of the state began to realize that it was not only the doctrines of Christianity that the Jesuit fathers were teaching but also obedience to another earthly power, the Pope. An imperial edict was therefore issued, forbidding the continuance of the preaching of this faith. At this the priests only doubled their zeal and preached publicly in bold defiance to the Emperor's commands. They were then ordered to leave the country, but the order was taken no notice of. Then began their systematic persecution. All foreigners were forcibly driven out of the country, and those who insisted upon staying were put to death. The priests and hundreds of Japanese proselytes were crucified for their faith. An edict was issued condemning all those who professed Christianity to be crucified, and a fearful slaughter took place. This persecution lasted for nearly a century and ended in the complete expulsion of all foreigners. Medicine had been introduced by the Dutch physicians, and they had had many eager students, but now its practice, as taught by the Dutch, was a crime punishable by death.

From then, until the country was opened

again by our Admiral Perry, Japan remained free from foreign invasion.

After Perry's conquest the foreigners gradually returned and were left unmolested, excepting when they violated all laws of propriety. Medicine was again introduced, but its study strictly forbidden by the authorities. Nevertheless the foreign physicians found themselves overwhelmed by crowds of eager students, many of whom bought their knowledge with the penalty of death. Some were decapitated, others were allowed to commit suicide by disemboweling. Soon however the spirit of progress took hold of the government also, and with the beginning of the present reign, some twenty-three years ago, foreign arts and studies were not only allowed but earnestly encouraged. Schools and colleges sprang up all over the country and the University was founded. Education is now opened to every Japanese and there is a complete public school system.

The main feature of the Imperial University, which is now recognized by nearly all foreign colleges, is its magnificent Medical Department, which, as far as completeness and thoroughness of teaching go, ranks with any school in the world. The course extends over a period of five years; and a sixth, or post-graduate, year is strongly recommended. The first year is devoted exclusively to theory; the studies taken up are anatomy, inorganic chemistry, physics, medical botany, and histology. During the second and third years the student dissects, uses his microscope, does a good deal of work in practical physics, and has his place in the laboratories. Physiology and organic chemistry and a very complete course in embryology are also gone through with during these years. It is not until his third year that the student sees the inside of a Hospital and then he begins the didactic study of medicine and surgery and its branches. The most of the third-year student's time is however devoted to materia medica, therapeutics and pharmacy. Practice is only taught during the fourth and fifth years, and during this time every student has his share of active work in the Hospital. The sixth year is more properly a "specialty year," during which the student is supposed to devote his time to some specialty. Strange to say a large proportion of the present students are taking up such specialties as medical jurisprudence, therapeutics, anatomy, etc., prefering to become teachers rather than practitioners. An able student in Japan will find no difficulty in the pursuance of his studies; for, if he has a certain average, the government will take charge of his education, remit his school fees and if necessary give him money for his board and finally send him to Germany or America to complete his studies under eminent specialists. Hospital positions are only obtainable by competitive examination. Wire-pulling is of little value.

The life of the medical student in Japan is of course totally different from what it is in America. A very military looking uniform is worn. Fencing and archery matches take the place of base ball and foot ball. Athletics are largely indulged in. The school fees amount to about $2.50 a month, and when four or five students club together they can live for less than three dollars a month. As a class they are usually refined and gentlemanly. At noon the student rests on soft white matting, in a picturesque tea-house, with a vista of minature waterfalls and bridges and fragrant plum and cherry-blossom trees in the distance, whilst a dainty little Japanese maiden in a gay gown serves him his lunch of beefsteak, rice, eggs and tea all for *six cents*.

There are Medical Societies in every large city of Japan, and Tokyo has about six or seven. The largest are the Tokyo Medical Society and the Sei-I-Kwai (Foreign Medicine Association). The latter holds an English meeting once a month, besides its regular meetings, and publishes transactions part of which are printed in English. These

Societies are very active, have large memberships and fine libraries.

Every city in Japan has its government hospital besides private institutions. Tokyo has about ten principal hospitals and a number of small ones. They include the City Hospital, the Naval Hospital, the University Hospital, the Children's Hospital, the Hospital for Diseases of the Lungs and Throat, the Maternity Hospital, the Eye and Ear Hospital, the Army Hospital, and the Insane Asylum. The Sanitary Bureau is most efficient and equipped with able officers. Quarantine Stations are located at every port and their regulations rigidly enforced.

Already Japanese physicians are being recognized abroad for their original investigations and untiring zeal. Dr. K. Miura, of Tokyo, has contributed valuably to therapeutics by his discovery of the new alkaloid, ephidrine, an extract from the *Ephedra vulgaris*. Professor Nagai of the Imperial University now ranks among the leading chemists of the day. Dr. Takaki, Surgeon General to the Navy, had two years ago performed thirty ovariotomies without losing a case—a record that no one need be ashamed of.

The latest experiments of European specialists are always carefully investigated in the laboratories of the University. Koch's and Pasteur's experiments were carried out in every detail. The latest medical and surgical works are translated into Japanese as fast as they are brought out; although every medical student is perfectly conversant with the German language, and very many with English besides.

In connection with these facts, it is interesting to learn, from the latest advices from Japan, that our country has agreed to revise the treaty with Japan on lines desired by the latter power. The *Mainichi Shimbun*, a leading newspaper in Tokyo, in speaking of the coming treaty revision says: "America is the first of all foreign powers to respond to our appeals, and with America rests the palm of giving effect to their liberality. America has helped Corea to achieve her independence, and America has interfered between powerful Germany and helpless Samoa, and it was America alone among all treaty powers, who returned her share of the Shimonoseki indemnity to Japan, and this last act is a worthy and fitting sequel to her consistently friendly proceedings in our country."

THE TIMES AND REGISTER.

There have come to this office the generous number of three copies of the first issue of a medical journal called the *Times and Register*, which is the successor of the *Philadelphia Medical Times*, the *Medical Register*, and the *Dietetic Gazette*. It has the general appearance of the *Register*, and the general character of the *Times*.

Those who admired the latter journals will probably regard this as praise; those who did not, will perhaps be disappointed that we cannot say more.

The number before us contains nothing above the standard of the latest issues of the *Philadelphia Medical Times*, which was once an admirable journal, but which fell into sad decrepitude before it entered upon the process of metempsychosis. If its editor improves his new opportunity, to show that he can produce a journal which will tend to elevate the standard of medical journalism, and not to debase it, his venture will have our best wishes, and, we have no doubt, will meet with success.

Ohio State Medical Society.—The forty-fourth annual meeting of the Ohio State Medical Society will be held at Youngstown, Ohio, May 22, 23 and 24, 1889. The President is Dr. P. S. Conner, of Cincinnati. The sessions of the Society will be held in Wick Hall, No. 134 West Federal Street, and the first session will begin at 2.00 P. M., Wednesday, May 22.

Reduced rates may be obtained on all railroads running to Youngstown, on certain conditions. Further information may be obtained from the Secretary, G. A. Collamore, M.D., of Toledo.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

LECTURES ON THE ERRORS OF REFRACTION AND THEIR CORRECTION WITH GLASSES. By Francis Valk, M.D., Lecturer on disease of the eye, New York Post-graduate Medical School, etc. Large 8vo, pp. 241. New York and London: G. P. Putnam's Sons, 1889. Price, $3.00.

The preface of this book asserts that it is offered to the general profession "as a simple and at the same time complete method for the diagnosis and correction of all the errors of refraction." As such, it seems to us a complete failure. Error begins in the first lecture upon Anatomy, to end only with the termination of the volume. Faulty construction, bad grammar, and incorrect spelling of proper names, meet us upon every page; whilst the sketches—with the exception of the cuts borrowed from the instrument makers—prominent amongst which is the author's self-styled "Valk's Improvement on Loring's Ophthalmoscope"—are frightfully and wonderfully made.

A book so full of faults as this one requires treatment at the hands of the reviewer which is far from pleasant to him; but the consideration which would spare the feelings of an author and thereby mislead the readers of a review would be an injustice to the latter. To tell the truth is the critic's duty, and the truth about Dr. Valk's book is that it is unworthy to be as a scientific or practical guide, and likely to lead astray those who may put their trust in it.

MATERIA MEDICA AND THERAPEUTICS, FOR PHYSICIANS AND STUDENTS. By John B. Biddle, M.D., late Professor of Materia Medica and Therapeutics in the Jefferson Medical College, etc. Eleventh edition, revised and enlarged, by Clement Biddle, M.D., U. S. Navy, and Henry Morris, M.D., Fellow of the College of Physicians, Phila., etc., with numerous illustrations. Large 8vo, pp. 607. Philadelphia: P. Blakiston, Son & Co., 1889. Price, $4.25.

Biddle's Materia Medica is about as familiar to students of medicine in this country as is Gray's Anatomy, and it has always been popular because it combined sufficient scientific detail with an easy and pleasant style. These two characteristics marked the earlier editions of this text book, and they mark the latest, which appears long after the death of the original author. His successors have kept his book in step with the progress of the age without changing the features which made it so popular at first. The book has grown much beyond its first proportions: but symmetrically and harmoniously. It is still one of the best works on materia medica and therapeutics with which we are familiar, and may safely be commended as a text book to both students and physicians.

PHOTOGRAPHIC ILLUSTRATIONS OF SKIN DISEASES. AN ATLAS AND TEXT-BOOK COMBINED. By George Henry Fox, A.M., M.D., Clinical Professor of Diseases of the Skin, College of Physicians and Surgeons, New York, etc. Parts 1–6. New York: E. B. Treat.

This is the second series of a well known work by one of the best dermatologists in this country. The six parts before us contain over one hundred pages of text, and twenty-four photographs, colored by hand. The plates are exceedingly graphic, and life-like, and are especially interesting as being exact reproductions of the conditions represented. They have not the brilliancy of lithographs, but they are more true to nature.

The whole work is sold, by subscription only, at two dollars for each part, and it is to be completed in twelve parts.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

257. The Brain and Nervous System. By E. W. Rush, M.D., Paris, Texas. 18 pages.

258. Science in Medicine. By Horace N. Mateer, M.D., Ph.D., Wooster, Ohio. From the *Post-Graduate and Wooster Quarterly*, April, 1888. 15 pages.

259. The Cortical Location of the Cutaneous Sensations. By Charles L. Dana, M.D., New York. From the *Journal of Nervous and Mental Diseases*, October, 1888. 31 pages.

257. This pamphlet contains a lecture delivered by Dr. Rush before the Teacher's State Normal School, at Aikin Institute, last July. It is stated to be a lecture on "Temperaments, or Temperamental Physiology, which embraces the Brain and Nervous System." In concluding it the author says he "has had to deal with truths and facts, elicited from subjective and objective clinical history of diseases, and he has long since learned to make the greatest allowance in human testimony, both in clientele, as well as in social statements."

258. Dr. Mateer's pamphlet contains his thesis for the degree of Doctor of Philosophy in the Post-graduate course of the University of Wooster. It is an interesting essay upon the claim of Medicine to be called a Science. It touches on the history of medicine, and the theories which have ruled in its development, and discusses the proper method for studying disease and the principles which should govern its treatment.

259. Dr. Dana's paper, which was read before the American Neurological Association, at Washington, last September, contains a learned and thorough discussion of the question whether, or not, the cortical areas in the brain for touch, pain and heat-sensation are identical with the motor areas for similar parts of the body. This question the author answers in the affirmative. The reasons for his opinion are founded chiefly upon a careful and exhaustive analysis of the histories of 142 cases, in which the symptoms were noted during life, and an autopsy was made after death. Four of the cases were under Dr. Dana's personal observation. The symptoms and the location of the brain lesion are noted upon charts of the brain published in his pamphlet, and the correspondence of the latter to the motor areas is very conclusively shown.

As a whole, this study is one not only of great interest, but also of great value to students of cerebral pathology and physiology, and is an admirable example of thorough and painstaking investigation in a very important and difficult field.

Notes and Comments.

Criminal Abortionists Punished.

The Paris correspondent of the *Lancet*, March 2, 1889, says that a rather curious case of a series of criminal abortions was recently tried at the Court of Assizes of the Eure, and caused a great sensation. This trial has brought to light one of the probable causes of the increasing depopulation of France in general, and of Normandy in particular. The accused, a man named Martin, was denounced by some of his own accomplices. He was a clockmaker by trade, and fifty-one years old. Seeing that it was impossible to deny the charge against him, he decided upon making a confession, and at the same time denounced his accomplices, as well as those who had submitted to the operation, which he performed with a reed. The list was a long one, but there were nineteen persons directly implicated. Martin, the principal, showed during the trial an imperturbable assurance, as if he failed to realize the gravity of the charges against him. "I wished simply," he said, "to render service to those who addressed themselves to me. As to the fees which I received, they were the just remuneration for my trouble." He added, with incredible cynicism: "Moreover, medical men, pharmacists, and herbalists have rendered justice to my ability in sending me patients." Martin was condemned to eight years and his accomplices to shorter periods of imprisonment.

Creasote in the Lung Affections of Children.

Soltmann says in the *Wiener med. Blätter* that with a few exceptions almost all observers speak well of the value of creasote in tuberculosis, and agree in saying that, even if recovery is not to be hoped for, marked improvement of the chief symptoms follows its employment. All the communications hitherto published relate to adults, and Professor Soltmann, of Breslau, is the first to record his experience of the remedy in children. He has, he says, given creasote in chronic lung diseases with little or advanced destruction, without considering the presence or absence of bacilli. After all due allowance is made for care in hospital, suitable nourishment, baths, good air, etc., considerable advantage is evidently derived from the administration of creasote, since cases which were not doing well began to improve unmistakably under increasing doses of creasote. He gives from two to seven drops of creasote a day. Soltmann's prescription is this:

R	Creasoti	gtt. iv–xiv
	Spir. æther.	gtt. vj–xij
	Aq. destil.	f℥iss
	Sacch. albi	℥iiss

A teaspoonful every two hours.

It merits especial mention that the creasote was well borne by all the children. Stomachache, nausea, vomiting, diarrhœa—inconveniences which often render treatment by creasote impossible in adults—never occurred. Even in high fever, which by all authors is spoken of as a contra-indication, the creasote was taken without disadvantage. That the large doses helped to give the good results is probable from Guttmann's experiments on the antiseptic power of creasote over many microörganisms. Very remarkable in many cases was the increase of appetite and gain in body-weight, the diminution of cough and expectoration, and the gradual disappearance of pathological lung-symptoms. Soltmann concludes that creasote exerts in chronic lung-disease in which there is a suspicion of tuberculosis a markedly favorable influence, especially where there is not much destruction of lung or other severe complication, and where there is not too high fever, the general strength being relatively good.—*London Medical Recorder*, March, 1889.

Damages for Death from Inebriety.

A man in New York drank to intoxication in a saloon and was drowned on his way home in a small stream. His widow sued the saloon-keeper for damages. The jury brought in a verdict for the widow and the case was appealed. In the Supreme Court the judgment was confirmed. The judge said the evidence was clear that the death of the plaintiff's husband was caused by his intoxication, arising in whole or in part by the liquor furnished by the defendant. The law in this case was the Civil Damage Act of 1873, of New York State, which provides as follows: "Every husband, wife, child, parent, guardian, employer, or other person who shall be injured in person, property, or means of support by an intoxicated person, or in consequence of the intoxication, habitual or otherwise, of any person, shall have a right of action against any person or persons who shall by selling or giving away intoxicating liquor have caused the intoxication in whole or in part."—*Quarterly Jour. of Inebriety*, April, 1889.

For Chronic Chills.

Daniel's Texas Medical Journal, April, 1889, says that for chronic chills, and that peculiar but very common condition of chronic malarial blood poisoning seen in swampy and other malarial sections, in which there is a "fever cake" or enlarged spleen, and a general dropsical tendency, there is no remedy, or combination of remedies, which has a better effect than that known throughout the South as Gadberry's Spleen Mixture. It is a solution of the oxy-sulphate of iron and potassa, and is made as follows:

℞ Pulv. ferri sulph. . . . . ʒi
Acidi nitrici . . . . . fʒi

Mix, and when reaction has ceased, add one ounce of some aromatic water, mint or cinnamon; to this add quinine ʒi, little by little, stirring constantly.

℞ Potas. citratis *vel* nitratis . . . ʒi
Aquæ menth. pip. *vel* cinnam. . fʒvii

Mix and dissolve and add slowly to the above, stirring constantly. Filter and wrap in blue or other dark paper, to exclude the light.

When properly made the mixture should be a perfectly clear, green fluid. The dose for an adult is a tablespoonful, three times a day, and in cases of long standing, it should be given every day for a month. On the days on which the chill is expected, the mixture should be given in anticipation, the same as quinine is given, and for children the dose should be proportioned to the age.

If old, dried sulphate of iron is used, the mixture is apt to be brown, and to deposit a sediment. If the sulphate is used in the natural state as found in the shops, and it is preferable, the mixture will be a bright green, and clear.

Care is necessary in adding the quinine to the acid solution of iron, to prevent its lumping; if added gradually and stirred with a grass rod it will dissolve like snow.

Pilocarpine in the Itching of Jaundice.

Dr. Goodhart states in the *British Med. Journal,* January 19, 1889, that he has found pilocarpine very effective in controlling the itching which is such an annoying symptom in many cases of jaundice. One patient had one-third of a grain injected subcutaneously many times, and always with the result that for the first twenty-four hours he was quite free, the second he was fairly free, and the third day he was getting bad again, and the dose had to be repeated. He has had six cases in all, and in none has it failed.

The Immisch Patent Metal Thermometer.

One of the most important aids to a correct diagnosis is a knowledge of the temperature of the patient. With our present means it takes fully ten minutes to ascertain this with our clinical thermometers. Further than this, the instrument is extremely delicate, easily broken, and often inaccurate. Immisch claims to have invented an instrument that does away with all these difficulties. His metal thermometer is supposed to register correct temperatures inside of five minutes or less, and it is claimed that it never varies. The instrument, however, has failed to stand practical tests. According to a report in the *Berliner klin. Wochenschrift,* March 25, 1889, Dr. F. Huebner has carefully compared it with other thermometers and has found that it is very inaccurate and not to be depended upon, and also that it takes fully ten minutes to reach the correct temperature. The instrument is very compact and well made, but in Dr. Huebner's opinion its good points are entirely overbalanced by its inaccuracy.

Febriline, a so-called "Tasteless Quinine."

Dr. R. G. Eccles declares in the *Druggists Circular,* May, 1889, that he has investigated a preparation sold under the name "Febriline or Tasteless Syrup of Amorphous Quinine (Lyons)," by the Paris Medicine Company, of Paris, Tenn., and finds that it contains no quinine at all. Instead of quinine quinidine is used, another alkaloid of cinchona bark, which is described as follows in the National Dispensatory, edition of 1879, page 1181: "Quinidia is not officinal. Being very slightly soluble, it should be administered in mucilage or syrup. Its lack of bitterness renders it convenient for administration to children, and its imperfect solubility is not disadvantageous when a slow or tonic action is alone required."

Chair of Surgery at Burlington, Vermont.

The Chair of Surgery at the University of Vermont has been filled by the election of Dr. A. M. Phelps, of New York City, who will begin his instructions on May 15. Dr. Phelps has already done service in the Medical Department of the University as Lecturer upon Orthopædic Surgery.

Treatment of Buboes.

In the Polish weekly *Gazeta Lekarska*, Nos. 15, 16, 17 and 18, 1888, Dr. Karol Szadek (pron. "Shadek"), house surgeon to the Kiëv Military Hospital, communicates an account of 274 cases of chancroidal buboes treated by him during 1881–86, the whole number of chancroid patients during the same period being 1084. The buboes, therefore, occurred in 25 per cent. of patients with soft chancres. The treatment consisted in absolute rest and the application of warming carbolic compresses on the appearance of cutaneous redness. As soon as fluctuation became distinct, he made a free incision, extirpated the affected lymphatic glands, scraped out carefully the whole abscess cavity with a sharp spoon, washed it out with a corrosive sublimate lotion, dusted on iodoform, and finally applied a tight bandage. The dressing was changed every four or five days. The wound healed in from ten to forty-five days, the average duration being about thirty days. In 5 cases, erysipelas, and in 12 eczema, occurred about the wound. Dr. Szadek never saw any toxic symptoms following the use of iodoform. He also treated, after the same method, 26 cases of buboes in syphilitic patients, and 12 of tuberculosis of the inguinal glands. The results were similarly very satisfactory, though here sometimes, especially in very exhausted tuberculous patients, recovery was rather slow.

A Disagreeable Summons.

A lawsuit interesting to medical men in obstetric practice has recently been tried in London. Dr. A. was engaged to attend Mrs. B. in her approaching confinement. In the dead of night Mr. B. summoned the doctor through the speaking tube at the side of the hall door. There was no undue delay, but still the anxious husband kept up such a din that the accoucheur declined to answer the summons, and refused to have anything to do with such an unpleasant patient. Another medical man attended the patient, who appears to have been delivered most satisfactorily; but not satisfied with the course of events, the discontented husband sought Dr. A. in his consulting-room, and attacked him both with tongue and fist. The magistrate, who presided at the subsequent action for assault held that a medical man was quite justified in declining an obstetric engagement under such circumstances, and fined the defendant accordingly.

NEWS.

—Southern California is to have a hospital for the insane.

—Dr. Craik succeeds the late Dr. Howard as Dean of the McGill Medical College, Montreal.

—The American Surgical Association will be held in Washington, D. C., May 14, 15 and 16, 1889.

—The American Climatological Association will hold its next annual meeting in Boston, June 24 and 25, 1889.

—Dr. F. E. Stewart has been appointed Demonstrator of Therapeutics in the Jefferson Medical College of Philadelphia.

—The next meeting of the American Association of Genito-Urinary Surgeons will be held in Newport, May 21 to 23, 1889.

—It is stated that Duke Karl Theodor, of Bavaria, who is an ophthalmologist, is about to establish an eye hospital at Meran, in the Tyrol.

—Dr. H. J. Harriman, of Revere, died at East Peacham, Vt., April 14, after a long illness. He was graduated from Dartmouth Medical College.

—The commencement of the Southern Medical College was held at Atlanta March 2, and degrees conferred 34 graduates in medicine and 17 graduates in dentistry.

—The municipal authorities of St. Louis have passed an ordinance to pay $500 to Dr. A. C. Bernays, to reward him for performing a successful laparotomy upon a policeman who was shot.

—Mr. Thomas Downs died in Philadelphia April 23, 1889, at the great age of ninety-four years. He was the father of Dr. R. N. Downs, of Germantown, and of Dr. Thomas A. Downs, of West Philadelphia. Mr. Downs was also the father-in-law of Dr. R. A. Martin, of Albion, Mich., the grandfather of Dr. Norton Downs and Dr. J. W. Mecaskey of Philadelphia, and the uncle of Dr. M. J. Grier, also of Philadelphia.

—The fourth session of the French Congress of Surgery will be held at Paris from October 7 to 13, 1889, under the presidency of Baron Larrey. The following questions have been set for discussion: 1. Immediate and remote results of operations done for local tuberculosis. 2. Surgical treatment of peritonitis. 3. Treatment of aneurisms in the limbs. All communications should be addressed to Dr. S. Pozzi, General Secretary, 10 Place Vendôme, Paris.

HUMOR.

To Young Physicians.—There is said to be a barber's sign near the Palais Royal, Paris, bearing the following legend in the vernacular: "Callileucocapillaire water which colors the hair white. For the use of young physicians and magistrates.—*Sanitarian.*

Mr. Rambo (at dime museum), in great alarm—"Nancy, do you see anything in that cage next to the monkeys?" Mrs. Rambo—"Yes, there's a lot of snakes." Mr. Rambo—(with recovered self-possession)—"So they are. Fine specimens too, aren't they?"

Pleasant for Uncle Jack.—(Uncle Jack returns from a long walk, and, being somewhat thirsty, drinks from a tumbler he finds on the table. Enter his little niece Allie, who instantly sets up a yell of despair.) Uncle Jack: "What's the matter, Allie?" Allie (weeping): "You've drinked up my aquarium and swallowed my free 'ittle pollywogs."—*Daniel's Texas Medical Journal.*

OBITUARY.

RESOLUTIONS ON THE DEATH OF DR. GROSS.

At a meeting of the Philadelphia County Medical Society, April 24, 1889, the following minute was unanimously adopted:

By the death of Dr. Samuel W. Gross this Society has lost an industrious co-laborer, a wise counsellor, and the profession one of its most brilliant ornaments. As a student, practitioner and teacher he possessed, with remarkable surgical acumen, unusual power of analysis and deduction, and his lectures, like his mental workings, were conspicuously clear, concise, logical and vigorous. He was an earnest student of the progress of surgery in all countries, with more respect for the experience of the present than the traditions of the past; never satisfied to stand still, and ever advancing with the progress of science, he kept his teaching always apace with the rapid strides of surgical knowledge. As an operator he was bold, conscientious and successful. Possessed of broad views, he was quick to recognize merit and to welcome truth by whomsoever presented. He took an active interest in all that pertained to the welfare of the profession and was ever ready to work for its promotion. He possessed positive convictions and was frank in their expression. As a companion he was genial and entertaining; as a friend generous and true.

HARVEY LINDSLY, M.D.

Dr. Harvey Lindsly, the oldest physician in Washington, D. C., died there April 28. Dr. Lindsly was born in Morris County, N. J., January 11, 1804. He was descended through both parents from English ancestry, the representatives of which came to this country two hundred years ago, and settled in New Jersey. He was prepared for college at the classical academy in Somerset County, N. J., and was subsequently graduated from Princeton College, which later conferred upon him the honorary degree of LL.D. At the time of his death he was one of the oldest living graduates of the college. He studied medicine in New York, and before completing his studies there he came to Washington, D. C., in 1827. He entered the National Medical College and took his degree in the year 1828. He became associated with Dr. Sewall, then the leading physician of the city, first as a medical student and then as a partner. Upon the death of Dr. Sewall, Dr. Lindsly succeeded to his practice. Sixty-one years ago he married Emeline C. Webster, a niece of Dr. Sewall, who survives him. Last year this aged couple celebrated the sixtieth anniversary of their marriage. He continued in active practice from the year 1828 until the year 1872, when he retired. Dr. Lindsly had a large practice, and in his day was associated with Drs. J. C. Hall, Thomas Miller, W. P. Johnson, Noble Young, J. F. May, Joseph Burrows, and other leading members of the profession. The two latter are still alive.

Dr. Lindsly was a member of the Medical society of Washington and of the American Medical Association. In 1858 he had the honor of being made President of the latter body. He was an honorary member of the Rhode Island Medical Society, of the Historical Society of New Jersey, and a number of other organizations. He was a contributor to a number of medical periodicals. For several years he was Professor of Obstetrics, and subsequently of the Principles and Practice of Medicine in the National Medical College of Washington. He was President of the Washington Board of Health for many years, beginning in 1833. For over thirty years he was a member of the American Colonization Society, and for a number of years he was President of the Princeton Alumni Association of the District of Columbia, holding that office at the time of his death.

Dr. Lindsly leaves a wife and four daughters.

EDITOR AND PUBLISHER,
N. E. COR. 13th & WALNUT STS., PHILADELPHIA.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

EFFERVESCENT SPECIALTIES

WM. R. WARNER & CO.'S
TRIPLE
(Effervescent)
BROMIDES

Advantages:—Useful in Headache, Nervousness, Sleeplessness, Migraine, Diurnal Epilepsy, Etc.

℞ Sodium Brom. grs. 15.
Potassium Brom. grs. 10.
Ammonium Brom. grs. 5.

Administer one teaspoonful in half a glass of water. Drink while effervescing. In Diurnal Epilepsy take a dessertspoonful three times daily until sense of taste is partly destroyed; after this reduce the frequency of dose, but keep the fauces in a benumbed condition.

WM. R. WARNER & CO.'S
CHALYBEATE
(Effervescent)
SALINE
(Ferric Saline Effervescens, Dr Means)

℞ 1 gr. Citro-tartrate of Iron and 20 grs. of Soda.

Dose.—A heaping teaspoonful of the salt, containing 1 gr. Citro-tartrate of Iron and 20 grs. of Soda, to be taken in a glass two-thirds full of water and drunk while effervescing. If a more decided effect is desired, warm instead of cold water may be used. In all cases this draught should be taken but once or twice a day, and then on an empty stomach, preferably before breakfast. No restrictions as to diet. One or two Pil. Digestiva (W. & Co.) may be taken at noon, before eating, as a dinner pill.

WM. R. WARNER & CO.'S
(ANTIPYRINE ET SODIUM SALICYLATE)
ANTALGIC
(Effervescent)
SALINE

℞ Antipyrine, 4 grs. Salicylate of Soda, 4 grs.
In each dessertspoonful.

Dose.—One dessertspoonful, to be repeated as often as the case may require. Almost a specific in Neuralgic Headache. Prescribed in all cases where Antipyrine is used, with more better and more certain results.

WM. R. WARNER & CO.'S
APERIENT
(Effervescent)
SALINE

A pleasant and excellent aperient and refrigerant, very acceptable to the stomach. Given in all cases indicating the need of an active aperient, and to be given daily to all patients under treatment with Dosimetric therapeutics. (See Wm. R. Warner & Co.'s Dosimetric Granules.)

Dose.—One tablespoonful in half a glass of water.

PREPARATIONS SUPPLIED BY ALL LEADING DRUGGISTS.

☞Samples of the above Salts furnished upon request.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO.,

PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co, Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

PROF. ALFRED STILLÉ, PROF. WM. GOODELL, PROF. D. HAYES AGNEW, PROF. H. C. WOOD, PROF. R. A. F. PENROSE, PROF. WM. PEPPER, University of Pennsylvania, PROF. J. M. DACOSTA, PROF. ROBERTS BARTHOLOW, Jefferson Medical College, PROF. CHAS. K. MILLS, Philadelphia Polyclinic.

The Philadelphia Polyclinic

Offers ample opportunities for observation and study, alike to EXPERIENCED PRACTITIONERS, who desire to REFRESH THEIR GENERAL KNOWLEDGE, or to take up SPECIAL LINES OF PRACTICE, and to RECENT GRADUATES who desire to PERFECT THEMSELVES in the SCIENCE AND ART OF MEDICINE—in its LABORATORIES, DISPENSARY CLINICS, HOSPITAL WARDS, and SPECIAL LECTURE COURSES.

☞ Classes are limited in number so that instruction may be personal. ☜

In addition to the facilities of the College Clinics, the Professors utilize, for the purposes of instruction, their services in the following large general and special hospitals:

PHILADELPHIA, PENNSYLVANIA, WILLS' EYE, EPISCOPAL, HOWARD, CHILDREN'S, ORTHOPÆDIC, AND INFIRMARY FOR NERVOUS DISEASES, JEWISH, ST. MARY'S, ST. CHRISTOPHER'S, ST. AGNES'.

Special Courses, Practical and Didactic, in OPHTHALMOLOGY, MASSAGE, and DIETETICS, have recently been established in connection with the appropriate Chairs.

Tickets good for daily clinics for six weeks from date of issue, or for one clinic weekly for three months.

Fee for any one branch, $15.00. General Ticket for thirteen clinical branches, $100.00.

Summer Course, July 1st to September 15th: General Ticket, $60.00. One branch, $10.00. One month, $25.00.

Seventh Annual Announcement may be obtained from

Lewis W. Steinbach, M.D., Sec'y,

At the College Building,

N. W. Cor. Broad and Lombard Sts.

OBSTRUCTION OF THE NASAL PASSAGES: ITS EFFECTS AND ITS TREATMENT.

BY C. A. BUCKLIN, M.D.,

NEW YORK.

Extensive obstruction to nasal respiration causes an individual to become an habitual mouth breather. When the obstruction is less complete, it causes a partial vacuum to be formed beyond the point of obstruction with each respiratory act through the nose. Mucous membranes become chronically congested when subjected to constantly varying atmospheric pressures which fall below the normal atmospheric pressure with each inspiration. It is self evident that mouth breathing or constant changes in the atmospheric pressure gives a rational cause for the production of catarrhal diseases.

During the stage of congestion we have acute catarrh. The stage of hypertrophy which follows chronic congestion is called hypertrophic catarrh. The atrophy which finally results from the increase of connective tissue in the mucous membrane occasions dry or atrophic catarrh.

Structural changes in the mucous membrane produce a change in the character of the mucus secreted. It is much thicker and produces the sensation of a foreign body on the mucous membrane. The constant attempt to dislodge this thick mucus, causes one to believe that there is a great increase in the amount of mucus secreted, when the quantity is in reality diminished. In health there is more mucus secreted, but its quality being normal, its presence is not appreciated and there is no desire to expectorate.

I am convinced as a result of clinical observation, that with the exception of persons one or two generations removed from tubercular ancestors and those affected with some infectious disease, nasal catarrh is developed as a result of obstruction in the nose and usually of obstruction due to some mechanical deformity in the bony walls of the nostrils.

Nasal obstruction also causes, indirectly, most of the incurable ear and annoying throat diseases of this latitude. It is also a cause of chronic bronchitis and catarrhal diseases of the eyelids.

Further, chronic congestion of the mucous membrane of the entire nasal cavities and of the connecting sinuses has a most decided influence in producing functional disturbances of the brain. Individuals so affected appear drowsy and stupid and complain of feeling so.

It may be said that these ideas are illogical, unfounded, and they may be received with incredulity by the profession.

For this reason all reference to obscure reflex nervous symptoms said to occur with nasal obstructions, will be avoided in this paper and only those easily demonstrated consequences, which arise from imperfect nasal respiration, will be considered. These my readers may be induced to accept, because frequent opportunity will offer in practice to verify the conclusions advanced. These conclusions have been forced upon me as a result of twelve years of careful thought and experimental investigation, combined with an extensive experience and extended observation of the methods employed and results obtained by Austrian, German, American and English specialists, in their daily hospital work.

I do not take the liberty of advancing a single idea which has not—as I believe—been fully confirmed by clinical observation, and which will not stand thorough investigation by others. The most convincing testimony in favor of the conclusions which the profession are asked to accept, is the history of intelligent persons, who have been operated upon. When the nasal obstruction has been properly relieved, these patients state, unsolicited, that they have been greatly relieved of annoying symptoms.

Nature of Nasal Obstructions.—These differ widely in their nature, their extent, and the amount of trouble they produce. The same amount of nasal obstruction does not produce anything like the same degree of annoyance with one individual, that it produces in another; while in a third person, possibly no annoyance would be experienced from a like defect.

Three per cent. of the children in the schools of New York have adenoid growths from the vault of the pharynx. These are a common cause of nasal obstruction, when they attain sufficient size. The other form of nasal obstruction most commonly found in children is hypertrophy of the mucous membrane covering the turbinated bones. Occasionally, a congenital mal-position of a turbinated bone is the underlying cause of the trouble. Deviations of the septum are very rarely seen until after the tenth year of age.

Children having the adenoid form of obstruction are invariably strumous. When the examination is made among half orphans, the percentage will run higher, than it will among public school children. If made among full orphans, the percentage will be found higher than in either of the other cases; which simply points more strongly to the strumous origin of the adenoid growth. This form of trouble is also very frequently complicated with enlarged tonsils.

Excessive hypertrophy very frequently develops in strumous children on the turbinated bones, as a result of frequent colds, nasal diphtheria, scarlatina, measles and other acute infectious diseases. This hypertrophy frequently produces a permanent nasal obstruction.

In adult life, in addition to the diseased condition of childhood, we have all possible deformities of the nasal septum, and polypoid degeneration of the mucous membrane of the nose, as causes of obstruction.

We have various neurotic conditions of the nose, which cause the mucous membrane to react so violently under the slightest irritation, such as a change of temperature, that its almost constant swollen condition produces a hypertrophy as a further cause of nasal obstruction.

We also have that strikingly peculiar so-called neurotic condition known as "hay-fever," which produces complete closure of the nose during the attack. In these patients, there is a peculiar susceptibility to poisoning by "rag weed," which blooms all along the Atlantic coast from Florida to the St. Lawrence River between the 1st and 14th days of August. I am told by my most intelligent patients, that this weed produces their attack of hay fever during its blooming period; that they can decide by examining the vegetation of a vicinity whether they will be able to avoid an attack of hay fever in that locality or not. They also tell me that at certain altitudes they are entirely free from hay fever. I think that most hay fever patients have the attack between the 1st and 14th of August. These troubles at this time, are certainly due to rag weed. Those patients who have hay fever severely commencing during June or July, are evidently poisoned by other forms

of vegetation. I have not observed such cases in my own practice.

In adult life there are three prominent factors which enter into the etiology of nasal obstruction. The first and most common factor is an abnormal relation between the bony walls of the nostrils, which so encroach on their caliber that there is not room for the normal swelling of the mucous membrane incidental to sudden changes of temperature.

All individuals in the same latitude are exposed to about the same changes in temperature. In some persons these changes always produce most annoying symptoms, which with each successive cold in the head are of longer duration, until at last the trouble becomes chronic. In other individuals, there is plenty of room for the normal swelling of the mucous membrane incidental to sudden changes in the temperature, without its producing decided nasal obstruction or more than temporary annoyances.

Individuals of the first class are constantly catching cold in their heads, while individuals of the second class are rarely troubled in this way.

The normal relations between the bony walls of the nostrils are disturbed by all deformities in the nasal septum, either bony or cartilaginous. The abnormal development of position of the turbinated bone, occasionally produces the trouble where there is not any deformity of the septum.

These bony deformities are the most common cause of nasal obstruction in adult life. They are frequently of sufficient magnitude to produce direct obstruction in the nose, but they most frequently produce obstruction indirectly by the unequal atmospheric pressures they cause the mucous membrane to be subjected to, during respiration. It is exactly in this special field, where the greatest success should be obtained, that the greatest failures have been made in treating nasal catarrh resulting from nasal obstructions.

These difficulties being mainly mechanical promise much better results from treatment, than difficulties which are largely due to constitutional diseases.

The second factor in producing nasal obstruction in adult life, is the nature of the mucous membrane which covers a bony or cartilaginous deformity in the nostrils. Cachexy and neurotic disturbances, produce conditions in the mucous membrane which cause it to swell excessively as the result of the slightest irritation. This explains why two individuals with the same bony deformity, suffer, under like circumstances, in such widely differing degrees.

The third factor in producing nasal obstruction is the climate in which the individual resides. In the tropics, but little room is necessary to accommodate the swelling of the mucous membrane, which in our latitude is necessarily so great, because of the sudden falls of the temperature. Consequently, individuals suffering intensely from nasal catarrh in our climate—which trouble has been the result of a bony deformity obstructing the nostril—will immediately improve upon change of residence to a milder climate.

Another form of nasal obstruction which very frequently escapes observation, is enchondrosis of the septum very low down. With a nasal speculum introduced and distended, the difficulty is not readily detected unless it is carefully searched for, because it becomes displaced by the speculum. The slight fall of the alæ of the nose with each inspiratory act, brings them in close contact with the thickened septum, making a valve-like obstruction which closes the nose to a greater or less extent with each inspiration.

Nasal obstruction from polypoid degeneration of the mucous membrane, is usually complete and very annoying. Relief is easily obtained by removing the polypoid growth which obstructs respiration. When the growths are very extensive, it will be found very difficult to prevent their frequent return.

Having considered the various forms of nasal obstruction, and how it brings about catarrhal diseases by producing in the air tract unequal atmospheric pressures with each inspiratory act, we will consider the effects of nasal obstruction on diseases of the eyelid, the ear, the brain, the throat and the lungs. We will also consider its special effect on the throat and lungs of tubercular patients.

I am thoroughly aware that the majority of my readers, may regard my attempt to show the relations between diseases of the eyelid, the ear, the brain, the throat, the lungs, the fatal termination in tubercular patients and nasal obstruction as groundless. I, however, state what I honestly believe my clinical experience has taught me, and having read the suggestions, I only ask my readers to accept such parts of these views as their clinical experience will confirm.

Effect of Nasal Obstruction on the Eyelid.—Ophthalmologists as a class acknowledge that one of the most frequent causes of chronic conjunctival disease is nasal catarrh.

It communicates, through the lachrymal passages, most annoying catarrhal disease to the conjunctival sac. The following four cases have been selected as samples of the evidence which has convinced me of the relations between nasal catarrh and conjunctival disease.

Case I.—Mr. L. came to me in 1880. He had been treated for some months by prominent specialists for trachoma. They had tried sulphate of copper and also nitrate of silver. The eyes had been growing steadily worse during the treatment. I tried the same treatment for two weeks, and must confess the eye-lids, which were one mass of granulations, grew steadily worse. The patient told me he had a badly obstructed nose and every time he caught an additional cold in his head, his eyes were decidedly worse. Acting upon this suggestion, without the slightest expectation of success, I thoroughly cleared his nose of all obstructions. In three weeks his granular eye-lids did not annoy him; and I heard within a month that he never has had any return of the trouble.

Case II.—Miss C., a case referred to me by Dr. Fields of this City, had been treated by skilled specialists every second day for about four years by the usual means of copper and silver. The opacity of the cornea continued to grow worse. She told the same story about the nose being obstructed and the eyes much worse every time she caught cold in her head. At the time I first saw her, she could not count fingers at a greater distance than four feet. The opacity of the cornea rapidly disappeared, and after four weeks she refused to come to the office any more because she considered herself well.

Cases III and *IV*—were two children treated for three months with sulphate of copper. I found they were not benefitted, and removed the nasal obstructions which existed in both children. They improved more in ten days than during the previous three months' treatment. The change for the better was so marked, that it attracted the attention of every one who came in contact with the children.

Effect of Nasal Obstruction on the Ear.—The ear is probably affected in two ways. The first is by direct extension of the inflammation to the middle ear. The second and more probable way is that the swollen condition of the mucous membrane of the pharynx causes the opening of the Eustachian tube to become obstructed in such a manner that the swollen end of the tube acts like a check valve. When we swallow, the air from the middle ear is partially exhausted, and the swollen mouth of the tube is so closed that a partial vacuum is constantly maintained within the middle ear. It is easy to understand what will happen in the blood vessels of the membrane lining this cavity if they are under a continuous partial vacuum. They will become chronically congested, the lining membrane of the tympanic cavity will hypertrophy or thicken, and we very soon have an incurable catarrhal disease in the middle ear. This condition has a tendency to keep up an annoying and unmusical buzz in the ear.

The fact that a large number of persons affected with catarrhal disease of the middle ear can hear distinctly when in a noisy railway carriage, or during the existence of any similar noise, is interesting and astonishing to the persons afflicted as well as to their friends. This phenomenon is especially prominent in proportion as the inflammatory disease has stiffened the joints of the little chain of bones which transmits the vibrations of the drum to the inner ear, which contains the nerve terminations necessary for appreciating sounds. When the stiffened joints of these little bones are set in vibration by a rumbling sound, any additional sound waves emanating from the human voice are easily appreciated. The moment the louder noise ceases, the sound waves from the voice are not of sufficient force to move these stiffened joints. With these individuals the stopping of a train interrupts entirely an animated conversation which was in progress while the train was running. This peculiarity is present in the most hopeless of incurable ear diseases.

I do not pretend by treating the nose to cure an ear which has been destroyed by catarrhal disease; but I do propose to arrest this horrible disease by proper treatment of the nose, if the treatment is undertaken before the ear is ruined. The slightest uneasiness or buzz in the ear should seriously attract immediate attention. You have only to look at the text books on otology and to observe cuts of Eustachian catheters made to inflate an ear, the Eustachian tube of which must be reached from the nostril of the opposite side, owing to a bony obstruction on the affected side, and no other testimony is required in support of the statement that cases of incipient catarrhal congestion of the middle ear have not received proper treatment. Treatment for catarrhal disease of the middle ear is usually commenced too late to be success-

ful; when it is commenced in time the recognized treatment is of such a nature as greatly to annoy the sufferer without giving him any chance of permanent benefit. The examination of the nasal cavities of school children is of more importance in averting future ear disease than the examination of the eyes is in averting future eye diseases.

Persons without nasal obstruction, having ventilation through the nasal passages sufficiently free to prevent the rarefaction of air during respiration, never develop catarrhal disease of the middle ear. The disease of the middle ear which comes on with the early secondary manifestations of syphilis must not, however, be confounded with catarrhal diseases of the middle ear by those who wish to criticize the above sweeping statement. The confusion which exists between these two forms of ear disease is very general among specialists.

Effect of Nasal Obstruction on the Throat and Lungs.—The throat and lungs become affected when the nose is obstructed, in three ways, viz.: by direct extension of the inflammation to these parts; by the rarefaction of the air within the parts during each respiratory act; and by the irritating influence of breathing directly into the air passages atmosphere which is cold, and laden with particles of foreign matter. When respiration is carried on through the nose this atmosphere is warmed, and the particles of foreign matter are removed by adhering to the moist mucous surface of the nose, which is especially adapted to receive such foreign bodies without injurious effects.

Persons frequently have a distressing cough for years, from continual irritation of the throat, caused by mouth breathing. Such a cough is greatly improved or entirely disappears upon the restoration of perfect nasal respiration.

Special Effects of Nasal Obstruction on Consumptive Individuals.—A consumptive person has a very irritable condition of the mucous membranes of the nose, throat and lungs, which for this reason are much more susceptible to the injurious effects of mouth breathing than the same organs of those who are not consumptive. The nasal obstruction in such cases should be relieved with the greatest possible rapidity.

Forced feeding, with intelligent use of pepsine, should be resorted to for the purpose of increasing the weight of the individual. The results should be carefully watched and if the weight increases steadily though very slowly, the prospects are encouraging. The individual need not be hastened away for climatic influences under these circumstances, for having changed one from a mouth breather to a nose breather, you have most materially changed the climate he lives in. Tubercle being a neoplastic or new cell growth without blood vessels, the general sloughing or breaking down of which is a result of its loss of nutrition, our object should be to avoid these consequences which lead so rapidly to a fatal termination. This can only be done by increasing the general nutrition of the body by forced feeding, and this cannot always be carried on without artificial assistance to digestion by pepsine. The increase or loss of weight decides quite accurately whether our efforts are meeting with success or not. Should the weight continue to decrease the individual should not be detained for the medical treatment of his nasal or throat trouble, but should be urged at once to avail himself of the only possible chance of averting the fatal tendencies of his disease by a speedy removal to a more favorable climate. The restoring of nasal respiration as a means of treating throat and lung diseases in consumptive persons will be successful in proportion as it is resorted to very early.

Effect of Nasal Obstruction on the Voice.—Singers, both professional and amateur, lose their voice as the result of nasal obstruction. Many have the most serious difficulty in attaining a given note. "E" being the note with which the difficulty is most frequently experienced. I have seen such a difficulty, which had annoyed a professional singer for twenty years, disappear one week after the removal from the nostrils of a bony obstruction which had disturbed the normal relations existing between those parts of the sound waves which are emitted through the mouth and nose. Any singer may observe the pure mechanical effects upon the resonance of a head tone by closing both nostrils when producing the tone. Those having the obstruction in the nostril suffer from more than its immediate mechanical effects—they also suffer from the chronic congestion of the mucous surfaces lining the entire respiratory tract. This congestion is directly due to the nasal obstruction, and as a secondary cause, most seriously damages the quality of any musical tone produced by the vocal organs.

Headache produced by Nasal Obstruction.—Persons having chronic congestion of the mucous membrane of the entire pharyngeal and nasal cavities complain of "full feelings" in the head. They are drowsy and find it difficult to remain awake at public

meetings or amusements. They suffer from mental depression and some with each cold in the head have intense frontal headaches due to obstruction of the frontal sinus.

The fact that the above described symptoms, existing in this class of individuals, are frequently relieved by restoring perfect ventilation through the nose is convincing of the relations existing between the nasal obstruction and the cerebral symptoms complained of.

Having considered how nasal obstruction produces such a variety of annoying diseases, we will consider the treatment of nasal obstruction.

Treatment of Nasal Obstruction.—The nature of the obstruction which is to be overcome must be thoroughly investigated before the means for its treatment can be chosen. Inspection frequently shows the anterior end of an obstruction which is so complete that we cannot see anything beyond it. The trouble may be due to chronic congestion of the mucous membrane alone. This can be decided only by using cocaine thoroughly, which will, in a few minutes, cause the temporary disappearance of the hyperæmia. We then have an opportunity to examine for further causes of obstruction, such as deformities of the nasal septum, or the turbinated bones, adenoid growths from the vault of the pharynx and true hypertrophies.

A carefully manipulated probe is of great additional assistance in determining the length, extent, and best manner of removing the bony deformity in the nose.

In obstructions due to simple congestion of the mucous membrane constitutional treatment with iron and quinine is sufficient to relieve the trouble.

It has been tried for years to reduce the thickening which occurs in the diseases of the mucous membrane of the nose by the use of all kinds of astringent sprays. The word failure is a mild expression for the negative results gained by this method of treatment. The only spray which should be used in the nose is an alkaline spray which is non-irritating deodorizing and antiseptic. I find a spray of the following description very valuable in cleaning the nostrils and neutralizing the irritating and decomposing nasal secretions both before and after operations. It is also valuable in the treatment of acute inflammation of the nasal mucous membrane.

This solution has been recommended by Carl Seiler of Philadelphia. It contains the following ingredients and is superior to any other alkaline spray I have used:

Sodii bicarb.	ʒ viij
Sodii bibor.	ʒ viij
Sodii benzoat,	
Sodii salicylat,	āā gr. xx
Eucalyptol,	
Thymol,	āā gr. xx
Menthol,	gr. v
Ol. gaultheriæ,	gtt. vj
Glycerini,	℥ viiiss
Alcoholis,	ʒ ij
Aquæ,	q. s. ad Oxvi

This formula gives a solution which is sufficiently alkaline to dissolve the thickened secretion adhering to the nasal mucous membrane, and as it is of the proper density, it is bland and unirritating, leaving a pleasant feeling in the nose. At the same time it is antiseptic and acts as a deodorizer, being in this respect far superior to Dobell's solution or any other non-irritating deodorizer and antiseptic. As it is, however, inconvenient for many patients to have so large a quantity of solution on hand, a Philadelphia drug-house (Wm. R. Warner & Co.) has made the solid ingredients into a compressed tablet, so that one, when dissolved in two ounces of water, will make a solution identical in its effects with the solution made after the above formula.

When there is no bony deformity in the nostril and the obstruction is due to a chronic thickening of the mucous membrane, good results may be obtained by making use of the contracting tendencies of a scar produced by the removal of a portion of the mucous membrane covering the turbinated bone, or by the application of caustics or galvano-cautery at the point where the contracting effects of the scar is desired.

I, however, discovered as early as 1880, that in the majority of cases the true cause of the difficulty was not a thickening of the mucous membrane alone, but a bony deformity which left too narrow an opening between the bony walls of the nostrils. In such cases the septum by its deflections or exostoses usually so encroaches on the caliber of the nostril as to make it impossible by the destruction of the soft tissues with cautery or caustics to obtain satisfactory nasal respiration, because the room gained by the destruction of soft tissue is lost as soon as collateral circulation is fully established.

Occasionally an enlargement or malposition of a turbinated bone, is also the cause of serious nasal obstruction.

My first attempts to remedy these bony

deformities were made nine years ago and they were the first thoroughly satisfactory ones ever made.

The instrument used was a No. 10 jeweller's saw, clamped in a sheet of metal to give the saw the requisite stiffness. One and one-half inches of the saw were left free to cut. The metal sheath was firmly clasped in a pin vice, which was driven into an ebony file handle. Seventy-five cents furnished the instrument complete, with a dozen blades. Although cocaine was not then in use, I obtained some most satisfactory results with this instrument in treating bony obstructions in the anterior parts of the nostril, owing to exostoses or deflections of the septum. I regard this instrument with such classic reverence that I give a cut of it in its original simplicity.

I was not long in discovering bony obstructions in the nostril, which were rather heavy for this little saw, some of them protruding at least one-fourth of an inch into the nostril and having a length of one inch. These difficulties led to the construction of a heavier and longer nasal saw, manufactured by Tiemann & Co., and kown as Bucklin's reversible nasal saw. It has two blades which are reversible in the handle.

Fig. 1.

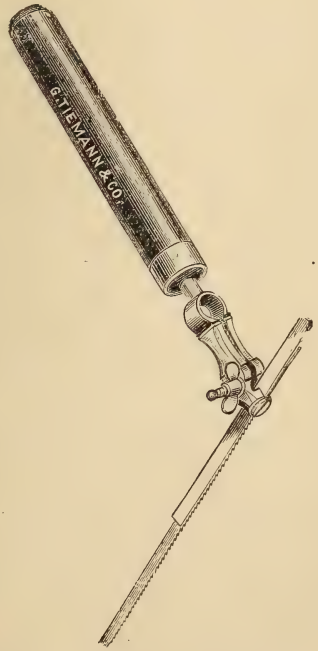

Figure 2 represents this saw as it is in use at present. With it I can remove from the nose any bony obstruction which is detrimental to perfect nasal respiration.

I am satisfied that from native timidity in a field where there was no precedent to follow I have erred in the past by failing to avail myself of all the room possible to

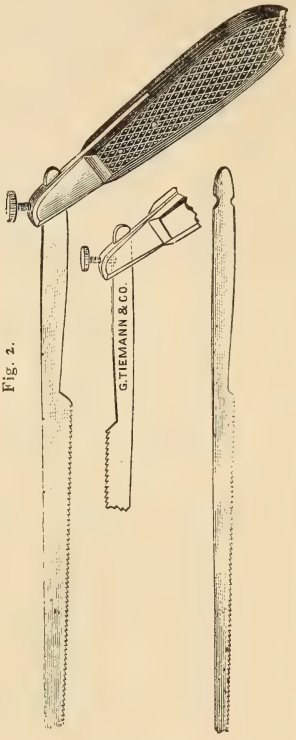

Fig. 2.

obtain a thorough removal of the deformity of the septum. I have tried to make good what I failed to do on the septum by the use of the cautery on the turbinated bones.

Exceptional cases are encountered where the displacement of the septum is so great that the difficulty cannot be relieved by its removal. In these cases the complete removal of one turbinated bone, although in its normal position, will usually give satisfactory breathing room. The rapidity with which the saw does this work is illustrated by the fact that the entire lower turbinated bone can be removed in less than one minute.

The complaints of intelligent patients plainly teach me that the mere opening of a hole through the nose gives little or no relief. The necessary requirement is a hole of sufficient size to admit sufficient air to prevent its rarefaction during the inspiratory act, and if the removal of the turbinated bone is necessary to secure this, it must be removed.

Dr. Bosworth of New York City has constructed a saw since I invented mine, but as far

as I know he did so without any previous knowledge of my instrument. He has done much to demonstrate that satisfactory results can be obtained by this method, and to expose the erroneous conception of that class of specialists who introduce an electric cautery into every nose they treat.

For the removal of excessive hypertrophies from the posterior extremity of the inferior turbinated bones and adenoid growth from the vault of the pharynx I can usually obtain better results with the steel wire snare introduced through the nose, the loop being carefully adjusted by means of a rhinoscopic mirror held in the other hand.

Special cases of this description may require the use of various forceps or the curette.

Conclusion.—The restoration of the normal relations between the bony walls of the nostrils by removing bony deformities is one of the most successful means of treating catarrhal diseases of the eye-lids, the ear, the throat, the lungs, and frontal headaches caused by catarrhal disease in the nasal passages.

The operations necessary to restore these normal relations are free from pain or danger when cocaine and carefully disinfected instruments are used.

The relief to the sufferer in nearly all instances has been simply magical. The changed nature of the mucous secreted by mucous membranes which have in old cases undergone extensive connective tissue changes, cannot always be remedied, consequently abnormal expectoration does not entirely disappear, in all cases.

206 West Forty-second Street.

REPORT OF A CASE OF SPINAL HEMORRHAGE.[1]

BY FREDERICK A. PACKARD, M.D.,

PHILADELPHIA.

The following case is of interest as one of hemorrhage into and possible partial rupture of the spinal cord in its upper portion, the patient having recovered in spite of the great extent of the consequent paralysis.

The patient applied for treatment at the Medical Dispensary of the Episcopal Hospital in March, 1889, giving the following history:

F. R., white, thirty-eight years old; was born in New Jersey; lives in Philadelphia; spar-maker by occupation. He has been married for fifteen years, and has had three healthy children. His family history is purely negative, except for the fact that one sister died in childhood from "some brain trouble." He has always been a very strong, healthy man, having had no previous illness, except malarial fever, of which he had attacks at various times until three or four years ago. He has been a *very* moderate drinker. Has had no venereal trouble of any kind.

He felt in his usual condition of health, and did a full day's work at his trade on September 22, 1888. In the evening he drank some old ale, not enough actually to intoxicate, but enough to make him a little uncertain in his gait. He went up stairs at 11 P.M., and when near the top of the first flight of fourteen steps lost his balance and fell to the landing on the first floor. He is positive that he fell from lack of balancing power and vertigo, and *not* from loss of power. The back of his head and neck struck the washboard at the foot of the staircase, while his back was bent over the edge of the lowest step. He endeavored to move, but found that he had no power in the extremities or trunk. He thinks also that common sensibility was lost from below the shoulders. His breathing, he remembers, was rapid, and there was a sensation as of a heavy weight pressing upon the chest. When found he was able to talk, see, and hear perfectly well, but was unable to use any muscles below the shoulder-girdle. There was no loss of consciousness, nor had he any convulsive movements. He felt as though the hands and feet were cold, and his impression is that they were soon found actually to be so by his family.

A physician was summoned and administered a powder that produced sleep. On the day after his fall he was undressed and put to bed. Hot irons were applied to his feet, and he was catheterized. He lay in bed perfectly powerless, except for head and neck, for two weeks, at the end of which time he became able to move his right shoulder. At about this time (*i.e.*, at the end of two weeks) there was noticed a linear series of blisters on the soles running from the ball of the foot to the heel. Nothing could be elicited to throw any light upon the question as to whether the blisters were traumatic, due to accidental contact with the hot irons, or trophic, although the former origin is much the more likely.

[1] Read at the meeting of the Philadelphia County Medical Society, April 24, 1889.

Soon after regaining some power in the right shoulder he became able to accomplish coarse movements with the arms. At the end of three weeks he regained some power over the right leg. The left leg remained powerless for two months. At the end of six weeks he was able to grasp an apple or other large object. At that time he tried to get out of bed with assistance, but was merely able to sit on the side of the bed, and that for not more than five minutes, owing to a feeling of being crushed from above. At this time (six weeks after his fall) he also first regained sensation, beginning in the thumb and index finger of the right hand and gradually extending to other parts.

During this time he had but little, if any, fever until the fifth week of his illness, when he had a pronounced chill followed by fever, and in four days another chill. After his second chill his "temperature reached 106°" on one occasion, at which time he was for a while delirious. He had no bedsores at any time (careful attention having been directed to the condition of his skin). His bowels were extremely constipated, and catheterization was necessary for two months. He ate well. Sleep was broken by a feeling of intense soreness across the back. He had no very severe pain, but felt as though a tight belt were being drawn about the chest and abdomen. He first noticed twitching of the muscles and extremities about three or four weeks after his fall.

Shortly after turning his sixth week he was propped up in a chair, after which time he gradually became able to walk with a great amount of assistance. He could not trust himself alone until two months ago (four months after his injury). At that time he thinks that he had regained as much sensibility as he now possesses.

His condition at the time of presenting himself at the Dispensary was as follows: General health seems good; he eats and sleeps well; the bowels are constipated, being unmoved for a week at a time unless aided; his urinary apparatus is apparently in good working order; he has no symptoms referable to the heart; he gets short of breath easily and, in addition to a sensation of weight upon the thorax, has a pronounced "girdle-pain;" he has not, nor has he had any vomiting or hiccough; his hearing is excellent, but his vision seems to him to be impaired; he has almost constant pain in the back of his neck, at times shooting over the occiput in straight lines on either side; his greatest complaint is of weakness in arms and legs, most marked on left side, and of coarse tremor occurring in all but a few positions that he assumes; he is able to walk about one block with the aid of a cane, but having accomplished that distance his right knee gets stiff and he is unable to lift the toe from the ground; he has both sexual desire and power.

Examination of the patient revealed the following conditions: Intelligent man, well nourished; speech natural; face and neck appeared entirely normal except for slight myosis. Examination of the pupils showed that they were equally contracted when shaded, but reacted feebly to light. There was no accommodative change in the size of the pupil. Heart and lungs normal. The urinary examination was negative, except for a slight excess of mucus, as revealed by the microscope. He stands with the knees in slight over-extension, the feet apart and the body inclined forward from the hips. On walking with the aid of a cane there is seen to be a marked spastic gait with some flinging of the feet in addition. On throwing the weight of the body from the hinder to the advanced foot there is seen to be a marked clonus in each, more marked in the advanced foot, and while produced in the forward foot by the weight of the body upon the ball of the dragged toes, it is, a little later, produced in the hinder foot by the effort of pushing the body forward by the ball. On closing the eyes there is marked oscillation, but apparently in great part from weakness, as the same symptom, to a very slightly less extent, occurs with the eyes open when he is deprived of his cane.

The spine is straight and regular. At the fourth and eighth dorsal spines are points tender on percussion. The muscles of the back are markedly wasted. Breathing is entirely abdominal at rest. Forced inspiration is accomplished practically entirely by means of the diaphragm and the muscles of the neck, including the platysma myoides. The intercostal spaces are plainly marked and not obliterated by the respiratory acts. On the occurrence of a deep inspiration there is marked bulging in the left lumbar and iliac regions as compared to the right, showing probably more powerful diaphragmatic contraction on the right side, or possibly more powerful action of the right parietal abdominal muscles. The grasp is weakened, especially and markedly on the left side. The nails show no transverse markings.

The sterno-cleido-mastoid, platysma, tra-

pezius, and levator anguli scapulæ of both sides are well preserved, as are also the supra- and infra-spinati. The serratus and latissimus dorsi are on each side wasted and feeble. Both arms appear wasted, the right slightly, the left markedly. On the right side the deltoid is of a size disproportionately large as compared with the arm; on the left side it is more equally wasted. Both arms can be abducted, the left with but small force. The right biceps is small but firm, the left is much wasted and flabby. The triceps on each side shows the same relative conditions. On each side the upper (clavicular) portions of the pectoralis major are in good condition, whereas the lower (sternal) portions are only seen on exertion and even then only with moderate distinctness.

Supination is very feeble in the left arm; in the right arm it is more forcible. The fingers are kept in a position more marked than semi-flexion, as is more markedly seen on the left side. Power of extension of the right wrist and fingers is feeble; on the left side extension beyond a right angle is impossible. The intrinsic muscles of the hands are wasted; on the left there is almost complete absence of thenar and hypothenar eminences.

Both thighs and legs on each side are wasted, the left much more than the right. The left thigh and leg, when the patient is seated, cannot be elevated even by great effort on his part. The right can be only slightly raised from the chair seat. There is very marked "clasp-knife" rigidity of the knees. There is no marked alteration in tactile sensibility. Of the superficial reflexes none could be elicited except the abdominal and cremasteric, and these were but poorly marked.

All of the "muscle phenomena" were marked, there being present: Knee-jerk in great excess, ankle clonus, paradoxical muscular contraction of the flexors of the ankle, great toe reflex, wrist and triceps reflexes. The phenomena excited by forcible flexion of the great toe existed only to the extent of contraction of the inner hamstring muscles.

In regard to the action of electricity, there was found to be diminution in Faradic excitability to a slight but noticeable extent, while to the constant current the excitability was much diminished.

Time did not permit of a detailed examination of all of even the principal muscles for qualitative changes. Those tested were the deltoids, biceps, quadriceps femoris, and the muscles of the calf. In all the formula presented was uniformly: 1. KClC; 2. KOC; 3. AnClC; 4. AnOC. The strength of current required to obtain KOC was five cells of a Fleming galvanic battery, more than were required to develop KClC; that for AnClC one or two cells more than were necessary to develop KOC, while many cells had to be added to obtain AnOC.

Examination of the eyes, kindly made by Dr. Randall, showed no abnormality except for hypermetropia, the fields of vision showing no change.

Taking the history and conditions present in this case, there would seem to have been hemorrhage into and around the cord with probably also partial rupture. That the lesion was hemorrhage or in the nature of partial rupture is made certain by the sudden onset in a previously healthy man of paralysis of motion and loss of sensation. That it was high up, in the cervical segment, is shown not only by the history of complete motor and sensory paralysis below the shoulder-girdle, but also by the signs presented at the present time.

The conditions no doubt have been a hemorrhage into and around the cord at about the sixth cervical segment, with probably partial rupture of the cord on the left side of the median line. This primary effect was followed by shrinking of the clot and restoration to some extent of the abolished functions. Secondary myelitis probably then occurred with, later, the descending degeneration of the lateral columns giving the greatly increased myotatic irritability below the parts supplied by nerves from the injured area. A secondary meningitis also probably occurred about the site of the lesion giving rise to the pain in the nape, and possibly also to the "girdle-pain" of which he now complains. There are present no signs to indicate any posterior ascending degeneration, but the lesion is so high up in the cord that they would be difficult of recognition.

Concerning the reactions obtained with the galvanic current, I do not know what significance the formula 1. KClC; 2. KOC; 3. AnClC; 4. AnOC may possess. It is rather hard to see how it can indicate degeneration from polar-cell disease, since it is so widely distributed beyond the site of the lesion as to preclude the idea of direct damage to the multipolar cells in the dorsal and lumbar regions.

—The Governor of Pennsylvania has signed the bill prohibiting the sale of cigarettes to children.

CASE OF CHYLURIA, WITH EXHIBITION OF PATIENT AND SPECIMENS.[1]

BY SOLOMON SOLIS-COHEN, M.D.,

PROFESSOR OF CLINICAL MEDICINE AND APPLIED THERAPEUTICS IN THE PHILADELPHIA POLYCLINIC AND COLLEGE FOR GRADUATES IN MEDICINE.

This patient and these specimens are exhibited at this time to give members an opportunity to see what is a rarity in this climate, and to make a record of the case. I trust to be able to present a more elaborate study of the condition at some future meeting.

The first specimen of urine exhibited was passed four days ago, and shows the characteristics of chylous urine to a marked degree. It looks like so much milk. The second specimen, passed two days ago, is not so marked; and the third specimen, passed this morning, is perfectly clear.

The patient is a colored boy, sixteen years of age, who was brought to Philadelphia from the island of St. Thomas nine years ago. I can obtain from his grandmother, who is an intelligent woman, no history of disease prior to four years ago, at this season of the year, when she noticed for the first time that he passed white urine. He was given a prescription by a physician, and in two weeks the urine resumed its normal appearance. There was no further trouble until about April 8, of the present year, when he again began to pass this milky urine. A week ago he applied at the medical department of the Philadelphia Polyclinic. After obtaining the history narrated, and having the patient urinate in my presence, a prescription was given which, to the mind of the patient, has exhibited startling virtues. It consisted of six drops, thrice daily, of aqua mentha piperita. The urine has become perfectly clear, as shown in this morning's specimen.

I have failed to discover in the urine either embryos or ova of the filaria sanguinis hominis. It has been kindly examined at my request by Professor Angelo Heilprin and Professor Joseph Leidy; but neither has found evidence of this parasite. I have also failed to discover it in the blood, either by day or night. The blood has also been examined (on one occasion, two nights ago, in this hall) by Dr. Griffith and Dr. Tyson, with the same negative result.

Now as to what we do find. The urine is acid in reaction and has a specific gravity of 1,010. On agitation with ether this milky appearance gives place to a slight cloudiness; showing it to be largely due to fat. On chemical examination of the urine, after the removal of the fatty matter, a notable quantity of albumin is found, but no sugar. A promised accurate chemical analysis has been prevented by the activity of our therapeutics—or the perversity of the disease. Under the microscope the milkiness, as stated in the report of Dr. Leidy, "appears to be due to an exceedingly fine and scarcely perceptible molecular basis, as well as to the presence of lymph corpuscles."

On three occasions I have found fragments of finely granular tube casts, and twice a few red blood-corpuscles. After solution in ether, the presence of oil globules is very plainly shown. Bacteria of various kinds were numerous in all specimens examined, even the one freshly passed. No unusual form was recognized as such. The long, slender rod described by Sir William Roberts was invariably present.

When first noticed, the urine all day long presented more or less the chylous appearance. That passed before me, at about twelve o'clock, noon, a week ago, was of about the color that would be produced by mixing two specimens, one clear, one chylous. Later, the milkiness was present only in the morning urine, and now it is not present, even in the morning. The clear specimen of urine shows neither oil, corpuscles, albumin, nor sugar.

The boy, although not fatty or fleshy, and probably much under weight, is not wasted. He is active, extremely intelligent, and possesses much physical endurance. Heart and breath sounds are normal. No disturbance in any other function has been observed and no lesion of any kind has been detected. Liver and spleen give normal percussion; there is no œdema or swelling anywhere. No enlarged glands, except a few shot-like enlargements back of the sterno-mastoid muscle, can be discovered. The chyluria has evidently run the same course as before, spontaneously intermitting; and I have thus been prevented from making extended observations as to the effect of diet, exercise, etc. The case seems to be non-parasitic, but I am not prepared to explain its origin with present data. I shall try to keep the patient under observation.

[1] Read at the meeting of the Philadelphia County Medical Society, April 24, 1889.

MUMPS IN AN AGED PERSON.

BY CHARLES W. MUSGROVE, M.D.,
AUSTINVILLE, PA.

April 20, 1889, I was summoned to see Mrs. Wolf, 84 years old, and found her afflicted with catarrhal fever. The catarrhal inflammation did not extend beyond the bronchial tubes, and by the tenth day the patient was convalescing very nicely. However, this day my attention was directed to a pain complained of by the patient during deglutition, occurring in the region of the angle of the jaw. On examination, I found the lower part of the left parotid gland slightly swollen, and tender to the touch, and the next day the entire gland was inflamed, and the right one slightly so, and tender to the touch. I now concluded that my patient simply had the mumps, regardless of her extreme old age. There were no symptoms except such as might be expected in this disease, and by the fifth day the inflammation appeared to be subsiding, and the patient doing extremely well.

On the morning of the sixth day I was sent for in a hurry, the messenger informing me that the patient was supposed to be much worse. On my arrival I found her with the following symptoms: Stupor, stertorous respiration, and jactitation. She could swallow liquids, when aroused from the stupor; but in spite of our efforts to save her life she died at 4 o'clock the next morning.

Deeming this a case of mumps with metastasis to the brain, occurring in an extremely aged person, I thought it might prove interesting to the readers of the REPORTER.

—The *Chemist and Druggist*, April 20, 1889, says that Dr. Lamal, of Anvers, has arrived at the conclusion that watery solutions of salts of morphine become turbid, colored, and of an acid reaction when kept for some time. This turbidity is due to two causes—the formation of mycelia, and the deposition of crystals. The coloration and the acidity have also in part a common cause, the formation of acid morphetine; more or less oxymorphine is also generated, which sets free a part of the acid in combination with the morphine. Oxymorphine has no therapeutic properties, so that these old solutions do decrease in narcotic strength. It would have been important for Dr. Lamal to have told us how much.

SOCIETY REPORTS.

INDIANA STATE MEDICAL SOCIETY.

FORTIETH ANNUAL MEETING, AT INDIANAPOLIS, MAY 1 AND 2, 1889.

President's Address.

The President's Address was delivered by DR. W. H. WISHARD, of Indianapolis, and was an interesting review of the practice of medicine during the past fifty years. He asked the question, have we as medical men kept abreast of the times? His answer was a masterly effort to prove that we had. The primitive Indiana doctors, he said, had not advantages of medical education. The Transylvania University, at Lexington, Kentucky, opened a medical department in 1817, which soon grew to be the second medical school of the United States. In 1819 the Medical College of Ohio, at Cincinnati, and in 1837 the Medical department of the University of Louisville were formed. Only twenty to twenty-five of the physicians of Indiana had taken one course of lectures in medicine in 1825. Ephraim McDowell was not a graduate in medicine, but after he had practised thirty years the University of Maryland gave him the honorary degree of doctor of medicine. The *Medical Repository*, of Philadelphia, was the only medical journal in the United States at the beginning of the early part of this century. Dr. Lunsford P. Yandell, of Louisville, first instituted the treatment of fevers more in accordance with modern ideas.

Dr. Wishard well remembers when quinine first came into use. He was given a prescription consisting of thirty grains of quinine, ten drops of diluted sulphuric acid and six ounces of water: dose, teaspoonful to be taken three times a day, with great care. He has known an old thumb lancet to descend as an heirloom in families for several generations, and it had drawn more blood than some regiments in the civil war. An old theory of mighty weight was, that if you drew blood from the right arm when pain was in the left the pain would be drawn across the heart and the patient would be killed. Obstetric business was of necessity in the hands of women in the early days. Physicians were scarce, women were robust, hardy nature required but little assistance. Early settlers were almost exempt from tuberculosis, diphtheria and cerebro-spinal meningitis; in winter, pleurisy and pneu-

monia raged. Four-fifths of the cases were treated by the old women until hopeless, then the doctor was called. The doctor was looked upon with suspicion in obstetric cases, and was not summoned until there was dire necessity; then the news spread like wildfire and the neighborhood turned out as to a wedding or a funeral. The good dame of fifty years ago would show with pride her ten or twelve sons and daughters. To-day we are shown one son or daughter and a poodle dog, sometimes only the poodle dog, as the hope of the family.

The doctor then made some scathing remarks on criminal abortion, and after some statements relative to the fortieth anniversary of the Indiana State Medical Society, — which was organized June 6, 1849, with twenty-eight physicians, of whom only five are now living — his interesting address was closed amidst applause.

The report of the Secretary showed a gain of six county societies and seventy members over last year. No doctor can be a member of the State Society unless he belongs to the County Association, and being a member of the latter makes him a member of the State Society. The whole number of members is twelve hundred. The Treasurer's report exhibited a prosperous condition of the financial affairs of the Society.

Dr. Kate Corey, a graduate of Michigan University and Superintendent of the Methodist Hospital at Foochow, China, was introduced to the society, and made a brief speech. The motion to make her an honorary member was passed without a dissenting voice.

The following officers were elected: *President*, Dr. J. D. Gatch, Lawrenceburg; *Vice-President*, Dr. S. Y. Yonte, Lafayette; *Secretary*, Dr. E. S. Elder, Indianapolis; *Assistant Secretary*, Dr. T. C. Kennedy, Shelbyville; *Treasurer*, Dr. F. C. Ferguson, Indianapolis.

Dr. G. W. Vernon, of Indianapolis, read a paper on

Broncho-Pneumonia in Children.

He thought the use of natural gas had become an important factor in this and other catarrhal diseases. In treating measles, whooping cough, etc., he said we should bear in mind the possibility of this disease: it may commence in the tubes and extend into the alveoli, or it may begin in the interstitial tissue.

Dr. Johnson, of Indianapolis, thought there were more recoveries from acute lobar pneumonia than from broncho-pneumonia. He considers catarrhal diseases essentially belonging to childhood.

Dr. G. W. Smythe, of Greencastle, read a paper on

The Hydro-Therapeutic Treatment of Typhoid Fever,

which was followed by a paper on

Atypical Typhoid Fever,

by Dr. H. McCullough, of Fort Wayne.

Dr. M. F. Porter thought there were more cases of the atypical than of typical typhoid fever. He opposed the routine treatment by cold baths.

Dr. Mendenhall said: there are 300,000 cases of typhoid fever in the United States each year, and 30,000 of these prove fatal. We should be interested in the disease.

The discussion on the subject grew quite strong, and the conclusion reached was that the whole question is simply one of diagnosis.

Dr. W. N. Wishard, of Indianapolis, discussed

Urethral Stricture in the Male.

Otis's operation is the only method by which he feels confident of success, as he is still dissatisfied with electrolysis.

Dr. A. C. Porter, of Lebanon, read a paper on

Nervous Sick Headache.

He said little was written and little known about this disease, though it is so frequent. He thinks a large majority of cases is due to a deficient supply of blood in the brain or some part of it. When due to stomach trouble, bismuth and fluid extract of quassia are good.

Dr. R. F. Stone, of Indianapolis, read a paper on the

Nature and Etiology of Tuberculosis.

He opposed bacteriology and all the theories of Koch. He disbelieves in contagion, thinks the germ theory a fallacious one, and antiseptics useful only so far as they induce cleanliness. This paper produced considerable discussion among the disciples of Koch.

Dr. James F. Hibberd, of Richmond, read an interesting paper on

Myxœdema,

and gave a report of a case under his care, and went extensively into the literature of this recently described and rare disease.

He pronounces it a distinct disease, with well-marked symptoms, not amenable to treatment, and says that, though persons may live for years, they never recover normal health.

Dr. G. W. Kemper, of Muncie, Ind., read a paper on

Antiseptics in Normal Labor,

and said that his experience in 900 cases of labor had taught him that antiseptics are uncalled for in cases in which the patient is surrounded by healthy environments, and he regards the complicated details of antiseptic midwifery in such cases as tiresome, expensive, and unnecessary.

TENNESSEE STATE MEDICAL SOCIETY.

ANNUAL SESSION, AT NASHVILLE, APRIL 30, MAY 1 AND 2, 1889.

The President, Dr. T. J. Happel, of Trenton, in the Chair.

The Treasurer's report showed a balance of $169.68 in the treasury. A report was made showing that after forty years of solicitation the legislature of Tennessee had at last passed a law regulating the practice of medicine. Though far from perfect, it was a great gain and should receive the hearty support of all. The Society recommended the following for appointment as a Board of Medical Examiners: Drs. C. Deadrick, Nashville; J. B. Murfree, Murfreesboro; D. D. Saunders, Memphis. A resolution requesting the legislature to pass the bill now pending requiring the registration of births and marriages was carried.

The following officers were elected: *President*, Dr. Duncan Eve, Nashville; *Vice-Presidents*, Drs. Henry Berlin, Chattanooga, J. B. Neil, Marshall, and J. P. C. Walker, Dyersburg; *Secretary*, Dr. E. D. Nelson, Chattanooga; *Treasurer*, Richard Cheatham, Nashville. The next meeting will be held at Memphis, the second Tuesday in April, 1890.

—Hypnotism, says the *Boston Journal*, has become very conspicuous in Europe of late. It has been used in the place of chloroform in some surgical operations at Paris, and when, in a recent murder case there, it was charged that the murderer had hypnotized the victim and forced her to kill herself, public opinion accepted the possibility of the fact in a way quite remarkable.

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND.

NINETY-FIRST ANNUAL SESSION, AT BALTIMORE, MD., APRIL 23–25, 1889.

Dr. John Morris, President, in the chair.

On Tuesday, April 23, after greeting the members, the President made his address on

The Physiology and Pathogenesis of Crime.

To prevent a man from becoming a criminal, he said, we must begin with him as a child. Every one cries out against immorality, but no steps are taken to create morality, to make morality a public sentiment; to make it a subject of national pride. Yet these are the prominent, the prevailing influences in Japan. There, crimes of violence and outrage are scarcely known.

Where the law of heredity is recognized, it is the duty of the medical man to forewarn parents and to suggest the proper education and surroundings, to render innocuous this taint of blood. The law of heredity obtains even more in moral than in physical traits. The family doctor has disappeared, but he must be brought back to occupy a higher and a wider field. We are born with unalterable tendencies which are not always evil. The Jew and the gypsy are examples of unalterable types. Ordinarily the physician treats the body alone irrespective of the mental organization. He is but half a physician. The body yields to the mind, the mind to the body rarely. The weakness or total absence of certain powers of mind is rarely noticed in children, and yet this observation is of the highest importance in shaping their future lives. The physician should be consulted in regard to the education of a family of children, and to do this he must have been trained by a long course of mental observation.

Marriage should be regulated by law. Paupers and criminals should be prevented from marrying. It is as harmful to bring insane children into the world as it is to drive them insane by bad usage. The habitual criminal, man or woman, should be deprived of the power to procreate.

On Wednesday, April 24, the Annual Oration was delivered by Prof. William Osler, the Physician recently elected professor of theory and practice of medicine in Johns Hopkins University,

On the License to Practise.

He spoke principally of the need of state boards of examiners to decide on the fitness of medical graduates to practise. In this country, he said, a man can follow the vocation he pleases, subject only to such restrictions as may be necessary for the public welfare. The right to regulate the practice of medicine rests with the state. At present this power is variously exercised in different states. In many no regulations whatever exist. In a majority of states, however, there are restrictions which demand evidence on the part of the practitioner that he has studied for a longer or a shorter period at an incorporated school. Practically the rule prevails that, with a diploma from a chartered school, he can begin at once, without any hindrance other than that relating to registration. The educational duties of the state do not here extend beyond the system of common and normal schools, though in a few higher university works are also undertaken. Special education does not receive support from the public revenues. Schools of law, medicine, engineering, theology, all the special branches of study, are private enterprises chartered by the state, and maintained by fees from pupils, or by the munificence of private friends. Certain privileges are granted to these institutions by the state, the most important of which, in the medical school, is the recognition of the diploma as a qualification for practice. So unsatisfactory, however, has this system proved, that there is, on the part of the public and the profession, a growing sense of the necessity for a radical change, as shown by the number of states in which bills have either been already passed or have been before the legislatures dealing with the problem, and if we wish legislation for the protection of the public, we have got to get it together, not singly. I know that this is gall and wormwood to many, but it is a question which has to be met fairly and squarely. When we think of the nine or ten subjects we have in common, we may surely, in the interest of the public, bury animosities and agree to differ on the question of therapeutics. In connection with license to practise there are, it seems to me, three courses open:

"First. A continuance in the plan at present prevailing, which makes the college the judge of the fitness of the candidate, and state supervision is only so far exercised that the diplomas are registered if from legally incorporated schools.

"Second. The appointment by the state or by parties so deputized of a board of examiners which shall, irrespective of diplomas, examine all candidates for the license.

"Third. The organization of the entire profession in each state into an electorate, which shall send representatives to a central parliament, having full control of all questions relating to medical education, examination and registration. These various plans are at present in operation in different parts of the continent. Colleges have practically had a monopoly for years, as the diploma has carried with it the privileges of registration. To all intents and purposes, the medical schools of the country are private organizations, and have direct pecuniary interests in the size of the classes. These chartered corporations are wholly irresponsible, without supervision by the state, the profession or the public. It would not be difficult, without fear of just rebuke, to bring a railing accusation against them for persistently acting in their own interest, and not in the interest of the public, but the time has passed for this. Yet it is surprising to think that so many men, distinguished in every way in their profession, cultured and liberal, still cling to and even advocate the advantages of an irresponsibility which has made the American system of medical education a by-word among the nations."

In the Section on Surgery, Dr. Randolph Winslow, Chairman, called attention to the subject of

Surgery of the Central Nervous System,

dwelling first on the importance of understanding thoroughly the general and topical anatomy of the brain, and then referring to the important results obtained by experiments on animals, by clinical observations, post-mortem examinations and by electrical stimulation of the exposed human brain during the performance of surgical operations. The cortex and base are most accessible and amenable to surgical procedure. Tumors of the brain are of more frequent occurrence than general practitioners think. W. Hale White and Victor Horsley have done the best work here. Cranio-cerebral topography is a new and very important study and has been mainly used in the surgical treatment of epilepsy, brain abscesses, etc. The study of surgery of the spinal cord is of more recent date. Few cases have been reported.

In the same section, Dr. Oscar J. Coskery reported a case of

Trephining for Cerebral Abscess,

with the result of removing the pus and giving motion to a paralyzed arm and leg, but the patient eventually died.

Dr. John G. Jay then reported a case of

Exsection of the Entire Ulna with Resection of the Humerus and Radius,

in a woman 49 years old. Complete anchylosis did not occur and the elbow remained movable to the extent of several inches, and the thumb and two fingers could be used. The operation was fully justified by the excellent results.

In the Section on Practice of Medicine, Dr. William B. Canfield, Chairman, spoke of

The Relation of Dusty Occupations to Pulmonary Phthisis.

He began by saying that the pulmonary diseases caused by the different kinds of dust had received a variety of names according to the character of the dust inhaled, but collectively they were all covered by the name pneumonkoniosis. Ever since Koch's discovery of the tubercle bacillus, and the gradually improved classification of lung diseases, there seemed to be doubt whether these dust diseases were tuberculous or not. The particles inhaled by miners in badly ventilated mines gradually overcame the action of the ciliated epithelium and penetrated to the alveoli of the lung, whence they found their way into the subepithelial layer where, unless rendered harmless or devoured by the greedy phagocytes, they set up a fibroid condition of the lung. Most writers agree that the fibroid condition is a barrier to the growth and multiplication of the bacillus.

Pneumonia, he said, results from something more than "catching cold." Sailors lead an exposed life and rarely have it. A large number of investigators have been looking for the specific organism. Salamon did some excellent work; Friedländer's pneumococcus was accepted for a time, but the investigations of Fränkel and Weichselbaum have shown Friedländer's organism to be only an accidental accompaniment of pneumonia. Good work has also been done by Gamaleia, Sternberg, Lipari and others. He referred to the theory of phagocytosis in connection with this subject and related his own experience in the bacteriological study of the organism.

Dr. W. S. Forwood of Darlington, Md., said that what was called "flint disease" by the workmen was very common and fatal in the quarries of Harford County. It begins insidiously with cough but not like consumption. It is generally fatal and ends like consumption. In answer to Drs. R. Winslow and A. K. Bond, he said that at the end of one year the lungs were permanently affected.

Dr. J. T. Wrightson, of Newark, N. J., said that lung trouble was very common and fatal among the hat makers of his city, but it was attributed more to drinking than to the dust.

On Thursday, April 25, in the section on Obstetrics and Gynecology, Dr. T. A. Ashby, the Chairman, spoke of the growing tendency to abandon empirical methods in gynecological work and the position of exploratory laparotomy. He then discussed the various diseases for which electricity had been used and then showed how much had been accomplished by it in a short time.

Dr. L. E. Neale then exhibited A New Obstetrical Forceps, which was a modification of Howard's modification of Tarnier's. He called it "Neale's Forceps." He claims superiority on the ground that it is all hard metal and can be made thoroughly aseptic, has Simpson's lock; the blades are narrowing, preventing rupture of the perineum.

In the section on Materia Medica and Chemistry Dr. T. Barton Brune, Chairman, read a paper on

Sugar Testing with Special Reference to "Alkaptonuria,"

in which he reviewed the various substances giving a sugar reaction, and spoke of the danger of trusting too much to one test alone.

In the same section Dr. W. B. Platt took up the subject of

Surgical Therapeutics,

in which he considered the curative, non-mechanical agencies employed in surgical cases, whether after accident, operation, or for surgical diseases. These he classified as Anæsthetics, Antisyphilitics and Antiseptics. In the first class he discussed protoxide of nitrogen, chloride of methyl, and cocaine.

Under antisyphilitics were mentioned mercury by inunction, hypodermic injections, and gray oil. The antiseptics were carbolic acid, creolin and iodoform.

Dr. Whitfield Winsey read a paper on

Hypnotics and Antipyretics.

In the former class he reviewed what is now

known of sulphonal, of which he spoke very highly.

Dr. H. Salzer read a very exhaustive paper on

Lavage,

and gave the indication for its use in adults and children, and his experience with it.

In the section on Anatomy, Physiology and Pathology, Dr. William H. Welch, Chairman, read an elaborate paper on Hydrophobia, in which he supported the opinions of Pasteur in regard to its nature and cited with approbation the statistics which Pasteur's supporters bring forward to show its efficiency.

Dr. F. T. Miles then read a paper describing a Case of Dilatation of the Stomach dependent upon Contraction of the Pylorus, in which tetany of a typical character occurred, and was speedily followed by death. He could find nothing in the vomited matter to account for it.

Dr. George I. Preston reported a case of Tumor of the Cerebellum pressing on the middle lobe.

Dr. I. W. Chambers submitted a paper on Cystic Tumor of the Lower Jaw, which was read by title.

Dr. J. D. Blake, in referring to Dr. Welch's paper, asked how the poison could be transmitted by the nerves alone. If injection into the blood does not kill, but makes the animal proof against future attacks, why not inject the substance directly into the blood of man to prevent hydrophobia?

Dr. W. C. Van Bibber said if the temperature stated would kill the organism of rabies, this should give a valuable idea in the treatment.

Dr. W. H. Welch remarked in conclusion that many facts about rabies were known which could not be explained. It was not understood how the virus was transmitted along the nerves, but the fact remains, and still further this did not seem to disturb the function of the nerve. It might extend along the lymph vessels of the nerves; we know little of the composition of the lymph. He did not mean to be understood as saying that the virus did not extend through the blood, lymphatics, etc., but that we have no evidence of this. In reply to Dr. Van Bibber, he said that the method of cauterization is a good one, but it does not prevent rabies. The virus must penetrate into the nerve to be transmitted by it and the chance of piercing a nerve in the skin by puncture is very small.

On Saturday, April 27, in the section on Psychology and Medical Jurisprudence, Dr. Richard Gundry, Chairman, read a paper on The Relation of the Physician to the Insane, and spoke particularly of the frequency of monomania and of the difficulties of recognizing true insanity by the unskilled, for a person may be entirely sane on many subjects and insane only on a few. A person totally insane has no recollection of a deed committed, while a person partly insane may remember the past partly.

PERISCOPE.

Simultaneous Amputation of Both Arms: Recovery.

At the meeting of the Philadelphia County Medical Society, April 10, 1889, Dr. W. W. Keen read the notes of the following case, which he puts upon record as a contribution to the statistics of multiple amputations.

Paul K., fifteen years old, was run over by a street car, at 5 o'clock P.M., on November 13, 1887. He was admitted to St. Mary's Hospital two hours later. The right hand, forearm, and elbow, as well as the left hand and lower part of the forearm, were crushed; both clavicles, also, were fractured. The boy had lost a great deal of blood before his admission, and was in profound shock when admitted; so grave was his condition that it was doubtful if he would live through the night. Dr. J. B. Roberts saw him late in the evening, and ordered whiskey and digitalis. At 10.45 o'clock P.M. his temperature was 97°; his pulse 120.

The next morning the temperature was 102.5°; pulse 142. At 1 o'clock P.M. his condition was very grave, but, as he had rallied from the shock, Dr. Keen decided to give him the only chance of his life, by amputating both arms. The right arm was amputated below the insertion of the deltoid; the left forearm at its middle. The moment that the first amputation was done, during the dressing of that arm by his assistants, Dr. Keen proceeded with the second, so as to lose as little time as possible. The patient bore the ether badly, and his pulse at times was almost imperceptible. Almost no blood was lost during the operations, the Esmarch bandage being applied above, but not including, the crushed parts. Of course, the most careful antisepsis was carried out. There was no need for hot bottles, etc., as his temperature was well

maintained. From the time of the operations his recovery was a perfectly steady one. For the first three days the morning and evening temperatures were about 100° and 102° respectively. From that time on the temperature fluctuated between 99° and 100°, reaching the normal by the tenth day.

On the third day after the operation the anterior flap on the left forearm began to slough; by the end of a week a piece two inches transversely by half an inch in the axis of the limb was completely separated. The gaping wound now exposed the end of the radius covered with granulations springing from both the periosteum and the medulla. In order to promote adhesion of the flaps extension was applied to them by means of adhesive strips, on which traction was made by a rubber band. This band extended to the end of a straight splint applied to the forearm, counter-extension being maintained also by adhesive plaster which was tacked to the upper end of the splint. At the end of two weeks the lips of the wound were united, and the splint was taken off. The right stump healed kindly, all the sutures being removed by the twelfth day. The boy was up ten days after the operations, and was sent home six days later to come to the hospital as an outpatient until he was entirely well. He was finally discharged at the end of January. Two small circular sequestra separated from the ulna and the radius of the left stump, and were removed January 9 and 24. The recumbent posture was the only treatment used for the fractured clavicles. They united very well, and with but little deformity.

Furunculus of the Ear.

In an interesting work by Dr. Löwenberg, a well-known aurist, entitled "Therapeutical and Bacteriological Studies on Furunculus of the Ear," the author gives as the results of his investigations the following summary of his conclusions: 1. Furunculus is caused by a microbic infection proceeding from external media, the invasion taking place by the excretory ducts of the cutaneous follicles. 2. The successive appearance of furunculi in the same individual proceeds from auto-contagion, which is effected by the transportation of cocci to the level of the cutaneous surface. 3. The same process may propagate the affection from one person to another or to several persons; furunculus is therefore contagious. 4. The entrance of microbes into the blood produces internal complications (metastatic abscesses) in certain cases of carbuncle, and even of furunculi, and often terminates in death. The author affirms that the micro-organism most frequently present in this affection is the staphylococcus albus, which was absent in one case only. The staphylococcus aureus and citreus were found equally often. In only one case were all three forms of staphylococci present together, and they were found in a certain number of unopened furunculi. Taking his stand on these researches, Dr. Löwenberg completely rejects the emollient treatment of this affection, which has hitherto been the classical one. He proposed, as long ago as 1881, to replace this treatment by another method which is antiseptic or antibacteric, destined not only to abort the affection at its commencement but also to prevent its recurrence. This he effects by the use of saturated solutions of boric acid and alcohol, which he drops into the ear in cases of otorrhœa, and in cases of unbroken furunculi he employs a supersaturated solution of boric acid in alcohol, from which the author has never experienced any bad effects. Milder solutions, he says, are of little or no use in these cases.—*Lancet*, April 6, 1889.

The Prevention of Conception.

At the Third General Meeting of Russian Medical Men at St. Petersburg, Dr. Petr N. Seidler read an interesting paper on the truly burning subject of the prevention of conception. While condemning an indiscriminate employment of any preventive means, the author believes that the practitioner is fully justified in interfering with conception in the following three categories of cases: 1. In women suffering with a more or less advanced pulmonary phthisis. 2. In women with organic cardiac disease. 3. In women suffering from profound anæmia, or failure of the general systemic nutrition with a hereditary tendency to pulmonary tuberculosis.

During a discussion following Dr. Seidler's communication, Dr. Nil I. Voblyi suggested that prevention is indicated, further, in such women as have once or oftener passed through extra-uterine pregnancy.

—The Connecticut Legislature has passed a bill prohibiting the manufacture or sale of oleomargarine colored in imitation of butter, and also prohibiting the sale of imitation cheese.

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Physician's Daily Pocket Record, - - 1.00
Reporter and Pocket Record, - - - - 6.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

SECONDARY OCCLUSION OF THE BOWELS FOLLOWING LAPAROTOMY.

With the aid of antisepsis and the technique of modern surgery we are now enabled to cope with the two greatest dangers of abdominal surgery, viz., septic infection, what for a long time was known by the name of "shock," and secondary hemorrhage. Of late years laparotomy has become an almost common operation, and although there are but few surgeons who can boast of having done it one thousand times like Sir Spencer Wells and Lawson Tait, yet the records of many hospitals show that the operation is becoming a more frequent one.

But now another great enemy to the success of laparotomies is agitating the minds of surgeons, viz., secondary occlusion of the bowels, which is caused almost exclusively by adhesions to the peritoneum. Dr. Alfred Obalinski, in the *Berliner klinische Wochenschrift*, March 25, 1889, speaks of three cases of occlusion of the bowels out of eighty-six laparotomies performed by him. Two of the cases were operated upon and recovered, the third came too late for treatment, and died. The causes for such adhesions are, according to the statements of various surgeons, first, the presence of foreign bodies, such as catgut, silk ligatures and the like; second, the presence of irritating fluids, such as solution of bichloride of mercury or carbolic acid, and third, overlooked wounds or lacerations of the peritoneum.

Dr. Th. v. Dembowski states that, after experimenting largely upon animals, he has found that adhesions can be produced with certainty only through the presence of foreign bodies or as a result of cauterization; also that the presence of iodoform, blood-clots, irritative antiseptic solutions, or even wounds of the peritoneum, never give rise to any adhesions. The experiences of Obalinski agree with the conclusions of Dembowski. In the three cases mentioned above, the adhesions were not in the vicinity of the sutures or ligatures nor near any lacerations of the peritoneum. He explains their cause as follows: Those portions of the bowels which are exposed to the atmosphere during the operation gradually assume a reddish color and then become covered with a fibrinous deposit. The same parts are necessarily handled both by the operator and his assistant, and it was at these portions of the bowels that Obalinski invariably found the occlusions.

The adhesions are not caused by septic peritonitis; for if such were the case, death would invariably follow. Early diagnosis of such occlusions is of the greatest importance. The principal and most infallible symptom is the anti-peristaltic movement of the bowels above the obstruction. The

symptoms of occlusion should not be confounded with those of peritonitis; for, although fever may accompany it and there may be distension of the abdomen, yet the latter will always remain soft and will not be sensitive. That this mistake has been made, however, has been frequently proved by autopsies where the peritoneum has been found to be smooth and shining and the occlusion to be merely a mechanical one.

Secondary occlusions of the bowel are far more easy to diagnosticate than primary occlusion, for, as they occur after laparotomy, they are watched for by the surgeon, and they may be treated before delay has precluded the possibility of recovery. Sibileau (*Annales de Gynécologie*, February, 1889) and many other authorities are against the immediate use of the knife, as soon as the existence of occlusion has been proved, and they state that in many cases such symptoms as vomiting and stoppage of the bowels, distention of the abdomen, collicky pain and the presence of albumin in the urine, may be overcome by large doses of belladonna. Obalinski, on the contrary, considers such symptoms a direct indication for speedy operation.

The prognosis of such cases is not so gloomy as is generally supposed. Sir Spencer Wells tells of eleven deaths from occlusion out of one thousand laparotomies. The prophylaxis of occlusion after laparotomy has been much discussed in gynecological societies, both here and abroad, and many theories in regard to it have been advanced. Muller (*Archiv. für Gynäkologie*, vol. xxiv, p. 1) suggests the injection of a sterilized solution of salt and water (seven per cent.) into the peritoneal cavity, in order to prevent the irritated surfaces from coming in contact with each other. A similar use of olive oil has also been suggested. Dembowski, by a large number of experiments upon animals, has proved the untrustworthiness of both of the above proceedings. The salt and water solution is absorbed too quickly to be of any value, and the oil causes suppuration and peritonitis. The same experimenter also proved that the use of iodoform, bichloride and carbolic acid, could not cause any adhesions.

In conclusion, it seems that reducing the exposure and manipulation of the bowels and peritoneum to the lowest limit possible would greatly lessen the chances of adhesions; while the occurrence of secondary occlusion should not cause the surgeon to despair, as the condition is easily recognized and in many cases not difficult to overcome.

CAPILLARY PULSATION IN AORTIC REGURGITATION.

General practitioners and life-insurance examiners are sometimes puzzled to decide whether or not obscure first and second sounds of the heart, heard over the aortic area, are due to a lesion of the aortic valves. It is well known that the distinctness or volume of a heart murmur bears no relation to the gravity of the lesion of the valves causing it; and the importance of determining with precision the existence or non-existence of the lesion must therefore be as great as far as prognosis is concerned in the case of a very faint murmur as it is in the case of a very loud one.

In such instances as we refer to, in which the diagnosis is otherwise doubtful, assistance may sometimes be obtained from the detection of capillary pulsation, according to the method suggested by Mr. W. S. Lazarus-Barlow, in the *Practitioner*, March, 1889. Capillary pulsation, it will be recollected, is a manifestation in the capillaries of the intermittent action of the heart. It is too slight to be detected by the sense of touch, but its existence may be inferred when the capillaries can be observed to grow alternately redder and paler with each systole and diastole of the heart. Of course, to be seen at all it must be looked for in a tissue richly supplied with blood and with

but a thin covering over the capillaries. Mr. Barlow's studies have led him to regard the mucous membrane of the lower lip as the best point at which to study capillary pulsation for practical purposes.

In examining for capillary pulsation he everts the mucous membrane of the lower lip and presses against it a microscopic slide. What is then seen in a typical case is a central patch into which no blood comes, owing to the pressure of the slide; but at some varying distance from the centre is a narrow zone in which the color intermittently becomes deeper red and then paler over the whole patch, while the edge seems to be in continuous movement, now encroaching upon, now receding from the area of greater anemia which lies next it. It is important in manipulating the slide to heed the caution insisted upon by Mr. Barlow, namely, that trembling of the observer's hands, or powerful pulsation of his arteries may lead to error in diagnosis by producing a varying anemia of the area under inspection, due to unsteady pressure of the slide against the mucous membrane. To constitute capillary pulsation, therefore, the flushings observed must correspond with the frequency of the heart beats.

Now as to the application of this phenomenon to the detection of disease. Mr. Barlow believes that capillary pulsation practically never occurs in health. In thirty-nine out of forty-six cases in which it occurred, the patients had some greater or less degree of affection of the aortic semilunar valves, as estimated by the condition of the second sound. Eighty-three per cent., therefore, of the cases in which it was found presented aortic valvular affection. The practical outcome of Mr. Barlow's observations is that capillary pulsation seems to be diagnostic of aortic disease, or—to be more exact—of aortic regurgitation, since twenty-eight of the thirty-nine patients had double aortic murmurs.

Mr. Barlow's paper is an interesting and valuable contribution to the value of capillary pulsation in the diagnosis of heart disease. But it is only just to say that the question cannot yet be regarded as settled in the affirmative; for while Fagge cites capillary pulsation seen under the finger nail as one of the symptoms of aortic regurgitation, Balfour, one of the most careful and accurate students of heart disease, declares that it has neither pathological significance nor diagnostic value, but is a "physiological curiosity" only. It is remarkable that such decided differences of opinion, as these statements of Barlow and Balfour indicate, should be held regarding the significance of a phenomenon so accessible to observation as capillary pulsation. This much can be said, it undoubtedly exists, and just how helpful its presence is in the diagnosis of aortic disease the readers of the REPORTER are as competent to decide as any other persons. Moreover, as intimated in the first part of this editorial, to determine the matter is of great clinical importance; for if, as seems probable, capillary pulsation is of diagnostic value in aortic regurgitation, then it may be possible to recognize this grave valvular lesion at an earlier period than is possible at present by other physical signs, and as a consequence the person affected may be placed in the best circumstances for the prolongation of his life.

SULPHATE OF SPARTEINE.

Sparteine, the alkaloid of Cytisus Scoparius, or the common broom plant, is a colorless liquid alkaloid, of a penetrating odor and extremely bitter taste, and soluble in alcohol, in ether, and in chloroform. It has been very little used in this country but is in common use in France and Germany, if we may judge by the number of papers which have been written upon it. In the *Deutsches Archiv für klinische Medicin*, March 14, 1889, Dr. L. Anton Gluzinski, of the University of Cracow, has a communication on the physiological and clinical action of sparteine. He finds that it

exerts a pronounced influence upon the circulation. This influence is more marked in cold-blooded animals than in mammals, and in the former its effect is more marked when sparteine is applied directly to the heart muscle than when it is injected into a vein or under the skin. The principal symptom of its action, according to Gluzinski, is retardation of the heart's action, and in a less degree also rise in the blood pressure—results which appear to be brought about by the action of the drug on the pneumogastric nerves and on the muscles. In toxic doses the inhibitory center of the heart is paralyzed; and death results from asphyxia.

The rapidity with which the effects of sparteine manifest themselves leads Gluzinski to recommend its employment when threatening or very severe symptoms develop in non-compensated heart lesions, and when the slower effects induced by digitalis cannot be awaited. It is, therefore, in his opinion, an adjuvant to digitalis and to be prescribed simultaneously with it. Moreover, it may be prescribed when digitalis produces no effect, or when its administration is for any reason contra-indicated.

It will be seen from the foregoing that Gluzinski does not regard sparteine as a remedy with a very wide range of application. It is, apparently, a heart stimulant less rapid and fleeting in its action than the ammonia preparations, and more rapid than digitalis. It has, therefore, a distinct though limited field of usefulness. The sulphate of sparteine, the salt most used, is freely soluble in water, and the smallness of its dose—one-twentieth of a grain at the beginning—fits it especially for hypodermic medication.

We may remind our readers, in conclusion, that Gluzinski's opinion as to the value of sparteine in the therapeutics of heart disease is substantially that previously stated by Jacobi, in his paper on the treatment of diphtheria, which was published in the Reporter June 30, 1888. Jacobi, however, uses it in much larger dose than that recommended in this editorial as the one proper to begin with. Since, therefore, experimental therapeutics and clinical experience seem to be in accord with regard to the utility of sparteine, it may be fairly assumed that they represent its actual value.

A REPORTER IN AN HOSPITAL FOR THE INSANE.

A good deal of interest has been aroused within a few days in Philadelphia, in consequence of an adventure of a newspaper reporter, who feigned insanity in order to investigate the workings of the Insane Department of the Philadelphia Hospital. This is not a new device, but it is a one which has opportunities of usefulness. In the present case the reporter learned by experience that it is possible to feign insanity so as to deceive for a time even those who have had much experience in diagnosticating the condition. This, however, is a fact which he could have learned with much less risk to his health and comfort by consulting any authority on the subject. He also learned the way in which hospital attendants sometimes treat the inmates when not restrained by the eye of the physicians: a thing he could hardly have learned without some such enterprise as he undertook. In doing this he has rendered a service to the authorities of the hospital in question, and a service also to his fellow men.

It seems as if there were no way in which occasional acts of cruelty to helpless insane persons can be prevented, and the greatest vigilance of humane physicians and superintendents is not sufficient to insure invariably kind treatment of these unfortunates. As this is the case, they may well be thankful to any person who is willing to become an inmate of an institution for the care of the insane in order to ascertain how keepers behave when they think there is no responsible person watching them.

Those who read the story of the reporter

of the *Philadelphia Inquirer* may well bear in mind that reporters who undertake enterprises of this sort do not usually spoil their descriptions by making them too tame, and there may be some exaggeration in the interesting account which this one gives of what he saw in the Philadelphia Hospital. But the story is published by a respectable and responsible paper, it is signed with the name of the reporter, and if it receives careful and wise attention, it may be turned to profit by the management of the institution.

STATE MEDICAL SOCIETY OF WISCONSIN.—A preliminary announcement of the meeting of the State Medical Society of Wisconsin has been issued. The next meeting of the Society will be held in Milwaukee, commencing Tuesday, June 4. All members of Committees especially, and all others who have voluntary papers to present, are requested to forward at once the titles and probable length of such papers, that they may be properly stated in the official announcement and programme of the meeting. As the President is absent from the State, all correspondence should be directed to the Secretary, Dr. J. T. Reeve, Appleton, Wis., who will also be glad to receive the names and addresses of any physicians deemed worthy of membership in the Society.

CHAIR OF SURGERY AT THE JEFFERSON MEDICAL COLLEGE.—The Trustees of the Jefferson Medical College have elected Dr. William W. Keen to the chair of Principles and Practice of Surgery and of Clinical Surgery, made vacant by the death of Dr. Samuel W. Gross. Dr. Keen was graduated from Brown University in 1859, and from the Jefferson Medical College in 1862. For two years he was a surgeon in the United States Army, and subsequently studied in Europe for two years. Later he taught, for nine years, pathological anatomy in the Jefferson College, and also conducted the Philadelphia School of Anatomy. Since 1884 he has held the chair of Surgery in the Woman's Medical College of Pennsylvania, and he also is Professor of Artistic Anatomy in the Pennsylvania Academy of the Fine Arts. Dr. Keen is well known as an accomplished anatomist, a skilful surgeon, an admirable teacher and a man of high personal character. Those who have had the pleasure of attending his lectures in the Philadelphia School of Anatomy will feel that the teaching force of the Jefferson College has received in him a very important addition.

PENNSYLVANIA STATE MEDICAL SOCIETY.—The Thirty-seventh annual session of the Pennsylvania State Medical Society will be held in Pittsburgh, June 4 to 7, instead of on May 21 to 23, as at first intended. It is to be hoped that there will be a full attendance of all the members.

PAMPHLET NOTICES.

[Any reader of the REPORTER who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

260. FIFTY-SIXTH ANNUAL REPORT OF THE MANAGERS OF THE PENNSYLVANIA INSTITUTION FOR THE INSTRUCTION OF THE BLIND, PHILADELPHIA. December, 1888. 33 pages.

261. THE CAUSES AND MODES OF DEATH FROM ECLAMPSIA, AND THEIR PREVENTION. By A. S. V. MANSFELDE, M.D., Quality Hill, Nebraska. From the *Proceedings of the Nebraska State Med. Society*, for 1888. 6 pages.

262. THE COMPARATIVE DANGER TO LIFE OF THE ALTERNATING AND CONTINUOUS CURRENTS. By HAROLD P. BROWN, Electrical Engineer, New York. 61 pages.

263. SUCCESS AND FAILURE OF ELECTROLYSIS IN URETHRAL STRICTURES, ESPECIALLY DR. KEYES' METHOD REVIEWED. By ROBERT NEWMAN, M.D., New York. From the *Philadelphia Medical Times*, December 15, 1888. 36 pages.

264. BIENNIAL MESSAGE OF RICHARD J. OGELSBY, Governor of Illinois. January 9, 1889. Springfield, Ill., 23 pages.

260. This Report of one of the best and most celebrated institutions for the blind in the world contains matter of interest in regard to its general management; but its most interesting feature for most readers will be the report of the Principal, Mr. Frank Battles. This gives an outline of the methods of instruction pursued in the Institution, and valuable suggestions in regard to the way in which the blind, as a class, should be regarded and treated. It can be warmly commended to the attention of all who

have an interest in any blind person or persons, and will abundantly reward any humanitarian for its careful perusal.

261. Dr. von Mansfelde gives his views in regard to the factors which most frequently contribute to bring about eclampsia, and the method best calculated to prevent its development or to cure it if it appears. For the former he recommends rational habits and dress, with examination for the occurrence of albuminuria and treatment of it—especially with a milk-diet; and for the latter morphia, chloroform, clysters, speedy delivery, and ergot. Bleeding he advises only in a limited number of cases.

262. The question as to the comparative danger to life of alternating and continuous electrical currents has been somewhat complicated of late by the arguments of persons interested in showing the comparative safety of one or the other method of lighting. After all, however, we believe that Mr. Brown demonstrates beyond reasonable doubt that alternating currents are far more dangerous than continuous currents of equal electric power. His pamphlet contains an imposing statement of facts and description of experiments, and leaves little room to doubt the justice of his conclusions.

263. Dr. Newman, in this paper, continues the defense of his method of treating strictures. It is principally occupied with a denial of the conclusions arrived at by Dr. Keyes from the results obtained in the case of one of his patients whom he turned over to Dr. Newman for treatment. The discussion is not altogether pleasant, and cannot counteract the impression that must be made by the fact that this method has so far failed to secure the approval of a single well-known specialist in genito-urinary diseases.

264. The part of Governor Ogelsby's report which is of most immediate interest for medical men refers to the working of the State Board of Health, which has done so much to elevate the standard of medical practice in that State, and to benefit the whole community. The praise accorded to this Board, and to its efficient Secretary, Dr. Rauch, is abundantly deserved, and other States might well study and follow the example they have set.

Literary Notes.

—The *Kansas Medical Journal* is the title of a new medical magazine, published monthly in Topeka, Kansas. The first (May) number contains 31 octavo pages of reading matter, and 9 pages of advertisements, including the cover. The subscription price is two dollars a year; single copies, twenty-five cents.

—The *Annals of Surgery* for May, 1889, has as its leading article a report by Dr. George R. Fowler, of Brooklyn, of a unique case of an air tumor of the neck caused by a hernia of the pleura in a case of pneumothorax. It is well illustrated by a lithographic plate and by a photo-engraving. The editorial articles take up the topics of Injuries of the Heart, The Treatment of Cerebral Abscess, Cancer of the Larynx, and the Treatment of Enlarged Prostate by Electrolysis. The Department of Index of Surgical Progress contains an unusually copious and exhaustive series of classified abstracts of articles from foreign and domestic sources, under about 40 different titles. The usual number of book reviews conclude the number. The *Annals* continues to maintain its position as a publication of high scientific merit.

Correspondence.

Euphorbia Pilulifera.

To the Editor.

Sir: So many physicians from all over the country have written to me desiring to know where Euphorbia Pilulifera may be obtained, owing to their attention having been directed to it by my article in the Reporter of March 16, 1889, that you will confer a great favor by publishing this note. It is prepared in the form of a Fluid Extract, by Parke, Davis & Co., of Detroit, Mich. They give the dose as f℥i, but I have used gtt. xxx in a wineglassful of water, three or four times daily, *pro re nata*.

Yours truly,

M. Graham Tull, M.D.

4807 Woodland Avenue,
Philadelphia,
May 9, 1889.

Notes and Comments.

Cæsarean Section.

On May 10, 1889, Dr. Howard A. Kelly, of Philadelphia, performed the Cæsarean section for the third time, delivering a well-developed male child. The obstruction to normal labor consisted in an osteo-sarcoma of the sacrum and coccyx which blocked up the superior strait of the pelvis and reduced the conjugate diameter to about one-third of an inch.

Treatment of Seminal Emissions.

Dr. J. K. Mitchell remarks in the *University Medical Magazine*, May, 1889, that the treatment of cases of nervousness from masturbation, or more properly nervousness *about* former masturbation, is commonly not satisfactory. He has, however, found one measure which has proved very useful in several cases under his care. He thinks it was originally suggested by Dr. John H. Brinton, some years since. It consists in the application of a blister over the sacrum. This measure he admits, is a somewhat severe one, but the patients are apt to have suffered many things of doctors, from advertising quacks up, and various treatments, mostly of a depressing or a merely palliative sort, with small results, and he finds that they offer little objection. What is more, the improvement is usually lasting. Of course, the use of the blister need not preclude

other and additional treatment, hygienic and medicinal.

The cases are, roughly speaking, divisible into two classes. In the first, the patient has emissions, usually during sleep, without an erection or with only an attempt at an erection; in the other the semen is only voided during erection or upon some irritation, mental or physical. In the former, the treatment should be tonic. Dr. Mitchell likes a mixture of dilute phosphoric acid and strychnia, as in the following formula:

℞ Strychniæ, ... gr. j
Acidi phosphorici dil., . . . f℥ ij
M. Sig. 25 drops in water after each meal.

In the latter, bromides, or better, a mixture of hydrobromic acid and bromide of soda or of lithium, have done good service. The usual precautions of course must be taken that no old stricture be left to keep up an irritation, and hygienic directions given—a hard bed, not too heavy coverings, light suppers, little meat, a sponge bath in the mornings, the bowels kept free, and all causes of sexual excitement avoided.

Dr. Mitchell then gives the following brief notes of three cases:

"A. B., æt. twenty-four, dyer, self-abuse from the age of twelve until fifteen, very frequently. After about one year began to have emissions involuntarily during the night, three or four times weekly. For some years now they occur every second night. Despondent, suffers with headache, weak back, general nervousness and costiveness. Heart and lungs sound, nothing wrong with urine. Pulse weak and seventy-four to the minute. Always has an erection before emission. Ordered phosphoric acid mixture, and a blister, four by four inches, over sacrum. Returned in five weeks to say had had emissions not oftener than once a week since blister. This patient reported himself as continuing well after several months.

"C. D., æt. twenty. Butcher. Masturbated until nineteen from childhood. Suffers little except from bad sleep and frequent emissions, with erection, several times a week. Eats much meat. Ordered hydrobromic acid, minims xv, with bromide of soda, gr. x, at night and four by four blister.

"Reported in a week that he had had no emissions, and at the end of a month that he had had only two.

"E. F., æt. twenty-nine. Weaver. Masturbated from the age of fourteen until twenty-one, once or twice daily. Has had emissions three or more times a week for 'some years,' sometimes without, but more usually with erection. Has pain in the chest and is languid, and nervous. Heart and lungs perfect. No urethral trouble and general health fairly good.

"Ordered hydrobromic acid mixture, and after two weeks' trial, with very slight improvement, blistered the sacrum. The resulting improvement has been permanent, and he has now emissions very rarely."

Analysis of Butter.

It is reported from Washington, under date of May 4, that the Agricultural Department has been making an analysis of butter from cows fed on cotton seed meal, which produces unlooked for results. The analysis showed remarkable points:

1. A low percentage of volatile acids.
2. A phenomenally high melting point.
3. A strong persistence of the reducing agent.

The first point is of importance as showing that mixing cotton seed with the feed of cows in the South will tend to raise the melting point of butter, thus rendering it more suitable for consumption in hot climates.

According to Professor Wiley the results are of great importance from an analytical point of view, since they show that a butter derived from a cow fed on cotton seed meal might be condemned as adulterated, when judged by the amount of volatile solids present. Since cottonseed-meal is destined to be a cattle food of great importance, especially in the southern part of the United States, this is a fact of the greatest interest to analysts and to dealers.

Voice Lozenge.

Dr. Hinkle, according to the *Chemist and Druggist*, March 30, 1889, recommends the following formula as the best for a "voice lozenge" in the ordinary hoarseness of singers and speakers. A small piece should be allowed to dissolve in the mouth just before using the voice:

Cubebs	½ grain
Benzoic acid	¼ "
Hydrochlorate of cocaine	$\frac{1}{70}$ "
Powdered tragacanth	¼ "
Extract of liquorice	5 grains
Sugar	13 "
Eucalyptol	¼ minim
Oil of anise	$\frac{1}{20}$ "

Black currant paste, enough to make 20 grains.

Treatment of Hæmaturia.

Professor Ultzmann, according to the *Deutsche med. Wochenschrift*, Feb. 28, 1889, suggests the following formulæ for use in hæmaturia:

℞ Ext. Ergotæ . . . . . gr. xv
Sacchari albi . . . . . gr. xxx
M. Div. in pulv. No. vi.
Sig. One powder every 3 hours.

℞ Aluminis,
Sacchari albi . . . . . āā gr. xlv
M. Div. in pulv. No. vi.
Sig. One powder every hour.

℞ Ext. Ergotæ . . . . . gr. xlv
Ol. Theobrom. . . . . gr. clxxx
M. Ft. suppos. No. vi.
Sig. Four suppositories a day.

℞ Argenti nitrat. fus. . . . . gr. xv
Aquæ destill. . . . . f℥ xvi
M. Sig. To be put in equal or double the quantity of cold water and used for injection into the bladder.

In the same way the following is to be employed:

℞ Ferri sesquichloridi . . gr. xvii ss *vel* xv
Aquæ destill. . . . . f℥ vi
M.

The Potter Railroad Hospital.

A memorial hospital, for the benefit of railroad men, of the Chicago, Burlington and Quincy line chiefly, is proposed. About a year ago, a railway king, Mr. Thomas J. Potter, died and it was agreed to honor his memory by a fine statue. Later his friends abandoned this plan and substituted for it the foundation of a hospital, to be called the Potter Hospital. The estimated first cost of this construction is stated at $25,000; the city in Iowa which contributes most generously will be the one chosen for the site of the hospital.

Sodium Bromide to Counteract Quinine Idiosyncrasy.

Dr. Krastilevsky has met with the case of a young girl, nine years old, affected with intermittent fever, in whom even small doses of quinine always provoked an erythema accompanied with intense itching. He succeeded in stopping this idiosyncrasy by the use of the bromides. By giving the patient every two hours a teaspoonful to a dessert-spoonful of a solution of bromide of sodium, one part to forty, he could administer the quinine with impunity, that is to say, without provoking in the patient either an erythema or itching.—*Bulletin Médical*, April 7, 1889.

Specialists for Asylums for the Insane.

At the meeting of the Alumni of Niagara Medical College, Buffalo, an address was delivered by Dr. C. A. L. Reed, of Cincinnati, on the great number of unrelieved cases of insanity among women, in the asylums of this country, by reason of inability on the part of the attendants to diagnosticate and treat uterine diseases. Some States have recognized this as a fact, and have ordered the appointment of one or more women physicians upon each asylum staff; but this does not, in Dr. Reed's opinion, reach the root of the trouble, for the number of these appointments is not proportionate to the numbers of the cases. He advises the abandonment of the present system of superintendents and assistants and the substitution of a visiting staff of specialists, made up from every branch of practice.

Dr. W. S. Tremaine, U. S. A., is reported to have endorsed the propositions of Dr. Reed, and added his conviction that rapidly made specialists are not desirable. No physician, he said, should assume to practice a specialty until he had passed ten years as a general practitioner.

"Take Your Medicine."

Dr. C. R. Illingworth says in the *British Med. Journal*, Feb. 9, 1889: As is only too well known, children and infants frequently refuse to take medicines, however palatable they may have been made. A great deal of trouble may be saved, I find, by fixing the cheeks firmly with the finger and thumb of the left hand, whilst the spoon is inserted with the right. By this method, which I first observed practised by a young married lady recently, the first essential in the act of deglutition is provided for, namely, a fixed point for the pharyngeal muscles. Ordinarily this provision is effected by closing the mouth, and there cannot, I think, be any doubt that the prevention of the natural process by the presence of the spoon leads in great part to the struggle to avoid taking medicine. When the approximation of the lips is prevented by the firm forward pressure of the finger and thumb, medicine may be poured into the pharynx without fear of its being spat out, and the most refractory child will, as a rule, discreetly swallow it. The practice of nipping the nose should, I am sure, be strongly condemned because of the risk incurred of forcing the medicine along the Eustachian tube.

Phenacetin and Antipyrin.

Professor Masius of Liege has communicated to the Belgian Academy of Medicine the results of a somewhat extended trial of phenacetin, which he has been making in his wards during several months past. In fevers of all sorts a reduction of temperature could generally be obtained by suitable doses; usually a dose of from fifty to seventy-five centigrammes ($\frac{5}{6}$–$1\frac{1}{3}$ grains) was sufficient for this purpose; it was found that the same effect could not be produced by smaller quantities, even when given repeatedly. Two grammes (30 grs.) during the twenty-four hours sufficed to keep the temperature down. The patients said that they felt a great deal better as the temperature fell; the pulse, too, became slower and stronger, and appetite and sleep returned under the influence of the drug. M. Masius also employed phenacetin as an analgesic not only in rheumatic, but in various other cases, with considerable effect. He did not, however, find that in this respect it was equal to antipyrin. It has been claimed for phenacetin that it has several advantages over antipyrin, such as more rapid action and an absence of disagreeable secondary effects, but according to the experience of M. Masius, though it is true that the lowering of temperature is more rapid than with antipyrin, it is of much shorter duration, besides which there is a liability to the occurrence of rigors and cyanosis, and neither its antithermic nor its analgesic action is so well marked as that of antipyrin. It has certainly the advantages of not disordering the digestion and of being cheap.—*Lancet*, March 9, 1889.

Diseases of the Antrum of Highmore.

Dr. Moritz Schmidt (*Brit. Jour. of Dental Science*, March 1, 1889) diagnosticates empyema of the antrum by making a small puncture below the inferior turbinated body with a fine canula, rather thicker and less pointed than a hypodermic needle, and curved like a Eustachian catheter. A pledget, soaked with 20 per cent. cocaine, is first inserted. He has diagnosticated in this manner an empyema in sixteen cases, and once a collection of colloid fluid. In twelve cases the exploratory puncture was made with a negative result, but without causing any injury. If pus is found he recommends free drainage through an alveolus. A silver tube is to be kept in.—*London Med. Recorder*, April, 1889.

NEWS.

—The Hospital of the Johns Hopkins University, at Baltimore, was opened with appropriate ceremonies May 7.

—The *Western Medical Reporter*, April, 1889, says that the Illinois Legislature has cut off the financial supplies of the Illinois State Board of Health.

—The Legislature of Massachusetts has appropriated $55,000 for the purchase of land and the erection of buildings for an epileptic hospital at Baldwinsville.

—Dr. Edward H. Williams has given $10,000 for the establishment of a separate department for convalescents in the new building for the Western Temporary Home, in West Philadelphia.

—Dr. Harrison Allen will deliver the next Toner Lecture at the National Museum, in Washington, on the evening of May 29. His subject is "The Clinical Study of the Skull, especially undertaken in Connection with the Morbid Conditions of the Jaws and Nasal Chambers."

—The authorities of the University of Pennsylvania have submitted a proposition to the Academy of Natural Sciences to remove the Academy collections and library to new buildings to be erected on grounds adjacent to the University, with a view to the mutual advantage of both institutions. The matter has been referred to the Council of the Academy for consideration.

—The *British Med. Journal*, April 27, 1889, says the Italian Ministry of Agriculture has, in compliance with requests from each of the localities, granted subventions to the Veterinary Schools at Turin, Bologna and Pisa, to promote the practice of vaccination against charbon (splenic fever) in the province of Sassari, and at Foligno and Civitavecchia, where the disease is causing great loss of cattle.

—Dr. Elliott Coues, of Washington, and formerly Surgeon, U. S. A., it is announced, is about to go abroad as a representative of the Theosophical Society, of which he is President. He intends to visit France, Egypt and India, with his gospel of mysticism. While in New York City, April 24, before taking the steamer, he lectured on modern miracles and ancient ghosts, before an audience composed chiefly, as one of the papers states, of women whose hair was short, with a few men whose hair was long. Dr. Coues is well known as a naturalist and as a contributor to the Smithsonian Institute publications.

—The Michigan House of Representatives has passed by a majority of six votes a Liquor Tax bill, which requires retailers to pay $600 a year; distillers, $1000; brewers, $200; wholesale liquor dealers, $800; wholesale beer and wine dealers, $500, and prevents druggists selling liquor except upon written application, which must be recorded in a public book. Under no circumstances can druggists sell by the drink or mix liquors with soda water or any other beverage to be drunk on the premises. The law will not go into effect this year.

—The daily papers state that contracts were signed May 7 by which the State of New York purchased for the electrical execution of condemned criminals three Westinghouse alternating current electric light dynamos. The State prisons at Sing Sing, Auburn and Clinton are each to have one of these deadly machines, which will be driven by the engines already in place. The current will be applied to the unfortunates at the same pressure used by the system for electric lighting, and the State's experiments have shown that death will ensue in less than 30 seconds.

—The *British Med. Journal*, April 20, 1889, announces that the three-hundredth anniversary of the invention of the microscope will be celebrated by the Executive Committee of the International Exhibition of Geographical, Commercial, and Industrial Botany, at Antwerp, in 1890. A retrospective exhibition will be got together from all available quarters, illustrating the history of the microscope, as well as an exhibition of the modern instruments of existing makers. A variety of conferences relating to technical and scientific questions connected with the microscope will be arranged. Already great interest is being expressed in the proposed exhibition.

HUMOR.

NOTHING will trip the light fantastic toe with more ease than a loose brick in the sidewalk.—*Merchant Traveller.*

IT MUST HAVE MADE the former Dandy Mayor green with jealousy to see the present one put on Waugh-paint and turn out White.—*Philadelphia Ledger.*

MISS MINERVA.—"If it is a proper question, please tell me, Mr. Longlocks, if the magazines ever return any of your poems? I have such ill luck myself." "No; never." Grumps (inaudibly).—"He never sends stamps."—*To-day.*

ANXIOUS MOTHER.—"I wish, Susan, that when you give baby a bath you would be careful to ascertain whether the water is at the proper temperature." Susan.—"Oh, don't you worry about that, ma'am. I don't need no 'mometers. If the little one turns red the water is too hot; if it turns blue it's too cold, and that's all there is about it!"—*Boston Commonwealth.*

OBITUARY.

F. S. McMAHON, M.D.

Dr. F. S. McMahon, of Courtland, Alabama, died April 12, 1889. He had been in poor health for two years. Dr. McMahon was born in Courtland July 10, 1836, and was graduated from the University of Pennsylvania in 1857. He practised his profession successfully until the breaking out of the war, when he enlisted, was appointed Assistant Surgeon, 16th Alabama Volunteers, rose step by step until at the close of the war he was Brigade Surgeon.

Dr. McMahon was a courteous gentleman, true, brave to a fault, and faithful in his dealings with all men. He died beloved by all, and deeply loved and lamented by his professional brethren.

MORTIMER O'CONNOR, M.D.

A cablegram received in Harrisburg May 3, announced the death of Dr. Mortimer O'Connor, in Paris, of pneumonia. Dr. O'Connor was born about sixty years ago in Ireland, and studied medicine at Glasgow. Immediately after graduating he was appointed surgeon in an English regiment of the line, and went to India, where he served during the Sepoy mutiny. On his return to England he was made surgeon in the Cunard steamship service between Liverpool and New York. In 1864 he was married, in Paris, to Miss Susan B. Haldeman, of Harrisburg, whom he first met on the steamer, and since that year he has resided in Harrisburg. His wife and son, Haldeman Mortimer, survive him.

About ten months ago a cancer, similar to that which afflicted General Grant, developed in Dr. O'Connor's throat, and his general health became bad. In company with his wife and son he spent the past winter in Algeria, but the climate did not agree with him and he went to Nice, and subsequently to Paris, where he died. Dr. O'Connor was a gentleman of liberal mind and culture, with very many friends.

WHOLE No. 1682.] MAY 25, 1889. [VOL. LX, No. 21.

BAKER'S EMULSION WITH HYPOPHOSPHITES OF LIME AND SODA

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO.,
PHILADELPHIA.

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request.

LAMBERT PHARMACAL CO., ST. LOUIS, MO.

The Philadelphia Polyclinic

Offers ample opportunities for observation and study, alike to EXPERIENCED PRACTITIONERS, who desire to REFRESH THEIR GENERAL KNOWLEDGE, or to take up SPECIAL LINES OF PRACTICE, and to RECENT GRADUATES who desire to PERFECT THEMSELVES in the SCIENCE AND ART OF MEDICINE—in its LABORATORIES, DISPENSARY CLINICS, HOSPITAL WARDS, and SPECIAL LECTURE COURSES.

☞ Classes are limited in number so that instruction may be personal. ☜

In addition to the facilities of the College Clinics, the Professors utilize, for the purposes of instruction, their services in the following large general and special hospitals:

PHILADELPHIA, PENNSYLVANIA, WILLS' EYE, EPISCOPAL, HOWARD, CHILDREN'S, ORTHOPÆDIC, AND INFIRMARY FOR NERVOUS DISEASES, JEWISH, ST. MARY'S, ST. CHRISTOPHER'S, ST. AGNES'.

Special Courses, Practical and Didactic, in OPHTHALMOLOGY, MASSAGE, and DIETETICS, have recently been established in connection with the appropriate Chairs.

Tickets good for daily clinics for six weeks from date of issue, or for one clinic weekly for three months.

Fee for any one branch, $15.00. General Ticket for thirteen clinical branches, $100.00.

Summer Course, July 1st to September 15th: General Ticket, $60.00. One branch, $10.00. One month, $25.00.

Seventh Annual Announcement may be obtained from

Lewis W. Steinbach, M.D., Sec'y,

At the College Building,

N. W. Cor. Broad and Lombard Sts.

PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

LECTURE.

PRACTICAL VALUE OF THE KNOWLEDGE OF PATHOGENY.[1]

BY PROFESSOR BOUCHARD,

PARIS, FRANCE.

PROFESSOR OF GENERAL PATHOLOGY AND THERAPEUTICS IN THE PARIS MEDICAL SCHOOL.

Gentlemen: To know why we do a certain thing, and what we do, is very rare knowledge, and for the physician it is a new thing. Medicine, as the other sciences which are practically applied, necessitates directing ideas for its intervention. Before the laws of resistance had been established by the science of mechanics, architects studied the old and most ancient monuments, which had resisted the trying influence of time, and then applied to new buildings the methods of construction which had preserved from destruction the works of the past, the excellence of which was in that manner empirically demonstrated.

Medicine has not overlooked empiricism; formulas have been compiled and adopted without knowing how the remedies act, but only on account of the observations of past centuries which have recommended them for the cure of certain diseases. This empirical therapeutics, however, did not prevent the physician from acquainting himself, following the example of Hippocrates, with the processes of Nature's medication; he ignored, however, the real cause of the cures, knowing only by external manifestations, which usually preceded the cure, that this naturalistic medication would relieve and help the symptoms. The particular indications were also not neglected, and the physician fought against the dangerous symptoms—pain, fever, and even insomnia. This is the therapeutics of symptoms and accidents; this is the palliative therapeutics which, some forty years ago, took up the name of physiological therapeutics and is still to-day in great favor.

I have always spoken in a respectful way

[1] Delivered at the Paris Medical School.

of palliative or physiological therapeutics, which I use to-day, when I cannot do better; but I should like those who use this method exclusively to speak of it with modesty. I admit that this method of therapeutics oftentimes relieves and even sometimes prevents death; this happens when, in a case of cardiac asystoly, the heart is stimulated to more energetic and regular contractions; and when, in a case of left pleurisy, the dangerous pressure upon the heart is suppressed by aspiration; but while to evacuate what is found in the pleura might sometimes prevent a man from dying, yet it will not cure his pleurisy.

Using the physiological method a high elevation of temperature might be prevented from becoming dangerous or the pain from becoming unbearable; intervention may be useful, may be satisfying to the suffering man, but it will not cure him; and the morbid process will continue its work, overlooking your intervention, and according to its natural laws proceed toward cure or toward death. If the patient recovers, he owes it to himself; nature has furnished the material for his cure.

Oftentimes the physician has very much contributed to the cure; he has attacked the cause of the disease, has interfered with the pathogenic process; he has very often done it unconsciously, the means having been furnished by empiricism. To the latter we owe the knowledge of administering quinine in intermittent fever, mercury in syphilis, the salicylates in acute rheumatism; these are precious acquisitions, which must not be overlooked to show that empiricism has done good. We are beginning to find out their mode of action, of some of them, and gradually they will be classified in the pathogenic therapeutics, of which method I said, ten years ago, that to it belonged the future.

In diseases the pathogeny of which is partly known pathogenic therapeutics pursues its researches in a logical direction, finding out what is better than drugs, the methods of treatment. Empiricism had given to it mercury, while pathogenic therapeutics has discovered its antiseptic property, and at once, more than a hundred antiseptic drugs. My excellent master, M. Charcot, said twenty-three years ago: "it is necessary for the physician to think anatomically"; one of his students said, some twelve years ago: "the physician must learn to think physiologically." These two precepts are excellent and one can say that Laennec, Cruveilhier, and Claude Bernard had prepared physicians to accept those precepts.

It is certainly useful that the physician should accustom himself to have, so to say, an internal view of the state of the parts in which the pathological process is going on. It is also necessary that he should be able to comprehend what interferes with the natural function of the part, and of the physiological disturbances produced by it in the other organs. But it is much more useful for the clinician and for the pathologist that they should accustom their minds to search the reasons why and how these lesions arise, why and how they persist or increase, and how they disappear. For the past ten years, I have always recommended that the physician should think pathogenically. What distinguishes scientifically medicine from natural history is this pathogenic point of view.

It is this which practically can enable one to apply curative therapeutics with some appearance of logic. This is a new view in medicine, and I shall surprise nobody when I say that a number of our professional brethren have never been embarrassed or preoccupied by it, having never employed it. This is because pathogeny is a new science. I must say, however, that in all the past life of medicine, physicians have always tried to find out the mode of action of causes and deduce from this knowledge a rational therapeutics; but they had false conceptions and made wrong deductions.

Only some thirty years ago has medicine slowly engaged itself in this pathogenic path, and pathogeny begins to-day to become beneficial to therapeutics by its discoveries. If we consider that Hippocrates was the heir of what he himself called "Ancient medicine," and that since his time more than two thousand years have been necessary to establish the nosology, to know what diseases are, by what lesions they are characterized, what symptoms reveal them, one is entitled to think that ever so many years will be necessary to know how diseases are produced, to penetrate into their intimate nature, to establish their pathogeny; and we might fear that thousands of years still separate us from the moment when we shall be able rationally to institute a pathogenic therapeutics. This would be true if each disease had a special pathogeny; but if the morbid causes are not numerous, then the number of pathogenic processes is limited. For the past ten years I have repeated and demonstrated that there are only four pathogenic processes. Certain diseases are the result of a previous interfer-

ence in the nutrition. Life can vary in quality and in intensity without stepping out of the physiological state. There are certain men in whom the cells elaborating the organic matter push this function to its extremest degree of destruction or oxidation, transforming the organic matter into water, carbonic acid, urea, etc. This perfection is however the exception, and is nearer to disease than to health. There are other men, and these constitute the majority, who, besides those perfect products, elaborate in a variable quantity incompletely transformed materials—such as uric acid, oxalic acid, the other organic acids and, in particular, the volatile fatty acids, etc.; this does not constitute and does not necessarily originate a disease. This imperfection of nutrition, which is the rule, brings on disease only when it is carried beyond certain limits. The quantity of transformed organic matter varies just as much as the different degrees of metamorphosis, even in a state of health.

One kilogramme of living human material can in twenty-four hours furnish one gramme (fifteen grains) of urea in the child; about forty centigrammes (six grains) in the adolescent; thirty centigrammes (four and a half grains) in the adult man; and twenty centigrammes (three grains) in the old man. In the same individual, not considering the age or the kind of feeding, many different conditions can influence the production of urea beyond or below the average daily quantity, without there being any cause or consequences capable of altering the state of health.

When we consider the intensity of nutrition only by the variations in quantity of one of the products of disassimilation, we observe that the physiological state is not allied to an invariable percentage of organic matter metamorphosis, but that it can exist when this matter is more or less completely transformed, or when this matter is more or less abundantly transformed. But there are certain limits of intensity and duration beyond which this deviation from the average nutritive type can bring about only a pathological state. I have demonstrated to you a type of these durable interferences with nutrition; they bring on diseases—such as biliary calculi, obesity, diabetes, gout, etc.—which are apparently different but the parentage of which has been established by clinical observations.

The physical, mechanical or chemical-morbid causes can involve, in a direct manner, the cells of a circumscribed part or the cells of the whole organism, and produce in them—without there having been previously an interference in the nutrition (a disturbance of life) of their functions that group of diseases of which the traumatisms and intoxications are the principal types, and which belong to a pathogenic process which I have designated under the name of "primitive cellular dystrophy." This is the simplest pathogenic process, but it is the least known and the most difficult one to study.

The morbid causes can also disturb the nutrition and the cellular function in an organ, in an apparatus, in the whole body, by an indirect action, using the intervention of the nervous system, and producing those diseases of nervous reaction to which I have devoted one year of my teaching.

Finally, infection constitutes the fourth pathogenic process, the knowledge of which is the most recent. This classification of the different ways in which diseases are produced you hear me refer to every year; I repeat it again to-day, for I am convinced that it is the expression of a just and prolific idea, which is not enough recognized. There is not a single disease the genesis of which does not recognize one of these processes, either isolated or in combination; the physician is therefore enabled to-day to think pathogenically.

Those who have a knowledge of pathogeny profit by it as well as their patients; this knowledge ought to be useful to others, but the generation of to-day does not familiarize itself with these notions; does not follow the oral lectures, but remains at home and makes their education by reading books which are still all built on an anatomical basis. Practitioners, although admitting the reality of the new doctrines, do not use them to direct their conduct.

Do the learned men of our profession derive all the benefit which is found in a knowledge of the pathogenic notions? I fear not, most of them only see one side of pathogeny, namely, infection. How many are they who take into consideration a morbid predisposition, diathesis or the premonitory interferences with nutrition? This enables us to see the most eminent masters in our profession use lithium for gout, or treat diabetes with the bromides. They do not comprehend that a remedy, which has a passing action, cannot, even if it has a momentary effect, overcome a chronic disease, which is chronic owing to a permanent vicious mode of life and which can only be

suppressed if life, that is, nutrition, is modified in a more durable form.

The surgeons of to-day protect wounds against *all* the microörganisms, to be more sure to prevent the influence of the pathogenic ones. If you treat in this manner, a wound in a diabetic patient, this wound will be cured by first intention; but at the same time, at some other part of the surface of the skin where no abrasion of the skin is to be found, will suddenly develop some formidable carbuncle. This is the result of the invasion at some portion of the subcutaneous system of the staphylococcus aureus, which, if it had only reached the surface of the wound, might only have produced a very slight suppuration. Many practitioners do not reflect on this point, others who think over it are discouraged; they do not see that in an infection, the infectious agent is not everything and that for its realization the interference of the organism is necessary; they overlook or forget that if the state of health is a safeguard against infection, certain deteriorations of health are favorable to the development of infectious agents and that there are nutritive changes which produce these deteriorations. They do not seem to know that the staphylococcus, which would not even produce the slightest reaction in a healthy man, will bring on pustules, boils and carbuncles in the diabetic patient. In the example I have just given, the wound has been carefully protected against the influence of the staphylococcus; and has united without suppuration; but the skin has not been protected everywhere, and the infectious agent, which resides everywhere around us, has penetrated into one of the follicles in which it has developed, having found a very favorable field for his development.

It is not the doctrine which is at fault in this case, but the physician who has failed to recognize the association between the two pathogenic processes, the premonitory disturbances of nutrition and then the infection; others are astonished when, during the convalescence of an acute abscess, they meet, owing to an exposure of the patient to cold, to fatigue, to a moral impression, with an unexpected complication, such as erysipelas They know that it is not a new infection, but that the primitive infection extends itself beyond the at first circumscribed limit of organic reaction. They do not know, however, that the nervous action has modified the nutrition and rendered the organism favorable to the microbe, which before the nervous shock had not been able to penetrate it deep enough. They accuse the doctrine of not explaining the clinical facts, because they have failed to associate the two pathogenic processes—the nervous reaction and the infection. To have a knowledge of infection constitutes progress; to see infection alone will prevent one from understanding many morbid processes. This scientific fault is detrimental not only to preventive or curative therapeutic, but also to prognosis and diagnosis.

If a fracture or a contusion have produced a large effusion of blood, and the skin is not injured so as to prevent the introduction of the infectious agent, a favorable prognosis will be given. But there are microbes in the intestines and you must not think that the epithelial layer is a great protection against them; they continually try to invade the organism, but the phagacytes prevent and destroy them after a short time. If, however, the life of the cells is suspended by the traumatic shock, the inhibitory action of which on nutrition has been demonstrated by the able experiments of M. Brown-Séquard, then phagocytism[1] is interfered with for some time, and as a result the microörganisms pass into the blood and

[1 Phagocytism is a theory advanced by Professor Metschnikoff, of Odessa, which explains the fight between the organic cell and the microörganism. He asserts that there are certain cells in the organism, whose function it is to envelope, to digest, to eat up any bacteria which penetrate into the organism. This can be very well studied in the most simple form of organic matter, the amœba; but while this living matter employs this process of absorption and digestion of bacteria for its nutrition, in the higher organism, this same function of certain cells exists, with the object, however, of protecting the organism against the invasion of pathogenic microbes.

Metschnikoff has given the name *Phagocytes* to the cells which have the property of digesting microbes. He has divided them into two classes: first, the microphagous phagocytes, which are the migrating cells or leucocytes, found in all the tissues, but especially in lymphatics and blood organs. Second, the macrophagous phagocytes, which are the fixed cells of connective tissue, the endothelial cells of the lung, the cells of the spleen, of the marrow of bones, and all the cells which have a large nucleus.

Whenever a foreign body, living or dead, penetrates into the organism, there is an assembly, a meeting of phagocytes, of leucocytes. If the foreign body is small enough to be enveloped by the isolated cells, it will be found in the interior of the phagocytes, such as is seen in malarial fever. If, however, the foreign body is large, the phagocytes will surround it and will form gradually an isolating envelope of connective tissue, which is what we observe in what is called eliminating inflammation; the hypertrophy of lymphoid organs in infection can also thus be explained, for those organs are really an agglomeration of leucocytes.]

reach the favorable spot. The surgeon astonished notices the development of a gaseous crepitation, fever appears, and infection is produced when he thought it impossible. Infection has taken place by a door which he thought carefully closed and which opened itself by a process which he did not suspect.

Phthisis is infectious, the tubercule bacillus is eliminated with the pus and fragments of pulmonary tissue, its presence is discovered in the sputa, which is a certain sign. What is the value besides these facts of the minutiæ of diagnosis? A bacteriological research gives you in ten minutes an absolute certainty, which the strictest and most careful clinical exploration will never give you. But the bacilli may not be present in the expectoration, even after a number of examinations, and precisely in cases in which the signs of auscultation are the more delicate. Are we not to fear lest a too exclusive notion of infection may lead the physician to neglect the education of his organs of sense and to diminish his skill in the difficult art of diagnosis? I could multiply examples to demonstrate how dangerous for the intelligence or practice of medicine it would be to overlook pathogenic processes and to attach ourselves exclusively to one of these processes. The notion of infection, when applied too exclusively, becomes excessive in its applications; the most difficult operations, owing to this knowledge of infection, have become much less dangerous. Still I am afraid it will become a too great stimulant to operative skill. The operation which was to be a curative one has already become exploratory. As I said a few minutes ago, for clinical medicine, the surgeon will become more careless and will neglect all the delicate and difficult means of clinical exploration; and, like the physician, he will allow himself to search for the absolute certainty in a more easy way but in a more dangerous one. Still, I cannot say that I am opposed to the exploratory operation, for I consider it a good procedure when necessity requires it. The exploratory operation becomes indispensable only when it is to be the first step in a probably curative intervention and when all other methods of diagnosis have failed. When diplomacy is powerless, there is some good in using a cannon; the same applies to exploratory operations.

The knowledge of infection has been very beneficial to the practice of medicine; but its practical application is such an easy one that if one allows himself to apply it too freely, some mischief may arise from it, were it only the delicacy of diagnostic means which is liable to be neglected or even the operative intervention which is liable to become temporary in character.

The therapeutic applications of our knowledge of infection have been very beneficial to both surgery and obstetrics; this knowledge has been extended to operations in all the serous cavities and to the greater part of the mucous surfaces. As to intestinal antisepsis in particular, I can say that it can render in certain cases the same services as external antisepsis in surgery. Interstitial antiseptic therapeutics has also given good results, but general antisepsis barring a few exceptions, is more theoretical than practical. A few years ago it was considered sufficient for therapeutical application to a disease to know its infectious nature; we cannot have to-day this same certainty, for we have gone deeper into the knowledge of virulence and infection. We understand that the infectious agent acts in different ways, that a virulent disease is not, as was believed, a battle between the microbes and the animal cells, but that the real action is more often directed by the cells toward the microbes, than from the microbes toward the cells; and that it is more a process of defence of the organism than attack on the part of the pathogenic element.

We have found, also, that the microörganisms are really dangerous through the poison they secrete. This was first asserted without any experimental proofs by M. Toussaint, then indicated by M. Chauveau as explaining more readily certain results of inoculation; from M. Pasteur it received the beginning of an experimental demonstration. It has finally been definitively asserted by M. Charrin, for the pyocyanic disease; by MM. Roux and Chamberland for gaseous gangrene; by MM. Chantemesse and Widal for typhoid fever; and by MM. Roux and Yersin for diphtheria. If the virulence of a certain disease is due to the toxicity of the matter secreted by the microbes, our therapeutical intervention must change, for poisons are not neutralized by antiseptics; yet, during the active period of the disease, when the infectious agent is multiplying rapidly, it is quite necessary that we should prevent its development, although we must not forget the poison which alone produces morbid accidents.

If this poison be secreted on an accessible surface, it can be evacuated or precipitated, to prevent it from being absorbed; if the absorption has already taken place, or if

the poison has been primarily formed in the middle of tissues, it can still be reached, burnt, by calling into action the process of combustion, or eliminated by the excreting organs. We can also combat its physiological effects by administering antagonistic substances. Amongst all these different processes, the elimination of the morbid poison is the one that is really established or demonstrated. I have demonstrated that in infectious diseases the urine carries out of the organism the greatest part of the soluble toxic substances which have been secreted in the body by the microbes during the course of the disease; that one can, in injecting the previously sterilized urine of an animal which died of the pyocyanic disease, produce in a healthy animal the principal and special symptoms encountered in this disease. MM. Charrin and Ruffier, after having injected into an animal the sterilized culture of the pyocyanic bacillus and having collected the urine, by injecting it into a healthy animal produced the characteristic paralysis met with in the pyocyanic disease.

The morbid poisons, and especially those of microbian origin, are then eliminated by the kidneys as the natural poisons are. If antiseptics can be used with advantage in the period of development of the general infectious disease, why should they be used in the later stages of the disease when the microbe ceases to be reproduced? But then, the virulent accidents have not disappeared, for they are slowly eliminated, this elimination seeming not to be complete before twelve or fourteen days. This better knowledge of infection which we possess to-day makes it possible to comprehend that in the treatment of infectious diseases antiseptics are useful sometimes but in some cases are absolutely irrational, especially when microbes or poisons no longer exist; and this is what occurs when, a long time after an infectious disease, accidents present themselves. These accidents are not infectious, they are not even toxic; but the poison has previously weakened the cells and injured their nutrition in a lasting manner. It is not with antiseptics that you will be able to repair the lasting injuries due to the infectious disease; it is only by agents which will generally modify the nutrition. There are many practitioners who, according to the modern doctrines, will treat a diphtheritic paralysis with iodine, oxygen, or carbolic acid; if better instructed in the contemporary pathogenic discoveries, they would return to the older practice and use the neutral salts, the alkalies, iodides, sulphides, and resort especially to nervous stimulation, to frictions, to hydrotherapy, to balneo-therapy, etc. This shows that the better we come to understand pathogeny, the better we are able to place by the side of new acquisitions the remedies obtained from empiricism, and the better we can explain the success which occurred in the old medical practice. It is said that to each specific infectious disease there corresponds a special microörganism; this is not so. A pathogenic microörganism of a determined species may produce nothing, or it may start a local lesion, or again it may bring on death without a lesion. The local lesion, if it develops, may be unique, circumscribed, diffused or multiple. The disease, when it occurs, may be trifling or temporary in character, or bring on death or become chronic. The streptococcus pyogenes can produce a phlegmonous inflammation, phlebitis, angioleucitis, erysipelas, meningitis, pyæmia, puerperal fever, etc.; this puerperal fever may be accompanied by a diphtheritic exudation into the uterus, infiltration of this organ, peritonitis, venous coagulations, metastatic abscesses, suppuration of the serous membranes; or again the puerperal fever may be without any lesions. As to the local lesions, suppuration is not necessary. Such a variability of action of one single kind of microörganism was thought impossible a few years ago. To-day, the fact being recognized, it is explained by the influence of the "*terrain*" (general state of the organism) which is variable with each individual. I certainly do not contest the influence of the *terrain;* I have sustained its influence and have tried to establish it as a factor at a time when it was regarded with suspicion. The influence of the *terrain* does not explain every thing, while the microbe can account for the differences existing.

Virulence is very variable; it has degrees, it may be weaker or may be stronger. A great many circumstances influence it; the field of development, especially, the composition of the nutritive substance; the presence of air or of too much oxygen can reduce or suppress it; too little oxygen stimulates it; it becomes weakened in a medium previously poor or in a medium which has been impoverished by the growth of the microörganism; it increases when it is animalized in a nutritive medium, such as has been lately shown by M. Chauveau, who restored the lost virulence of the bacillus of malignant carbuncle by cultivating

it in broth to which blood has been added. It is rendered much stronger when it passes from an inert medium into a series of living organisms; this increase in virulence varies according to the animal species, so that it can be reduced by transplanting the microbe from a more favorable animal species to a more refractory kind.

Some of these conditions are encountered in human pathology. When the streptococcus, moderately virulent, multiplies itself in an irregular wound, in fetid cloaca in the uterine cavity, its virulence increases and can produce dangerous symptoms, which are much rarer when the streptococci are found on a wound exposed to the air. Meeting so many varieties of action, we may ask ourselves, Which is the type of the normal virulence? and we are forced to conclude that this normal does not exist.

Among the chemical functions of the pathogenic microbes, there is one which produces the toxic substance; this function is more or less active, feeble or strong. According to the case, the same microbe has a negative virulence, a feeble, a moderate, an intense or an excessive one. In this manner we explain the variability of action of the same virus, which misled the adepts of the new doctrine and made them doubt the validity of their belief.

Virulence can extinguish itself; the microbe can even cease to develop. It is not dead, however, but remains asleep in the organism, and one day awakens as a result of a local traumatism or of some disturbance of the general health; it has recovered its virulence. The return of a disease succeeds upon a short sleep. The return of the disease at the same place or at some distant point from the one primarily infected is the effect of the awakening which follows a very long sleep, and is a clinical justification of what M. Verneuil has expressed in one word, the *latent microbism*.

All this, however, appeared in contradiction to the doctrine; one could not understand why, in certain women, the regular appearance of the menses would bring on periodically an erysipelas without a new infection. The resurrection of a microbe is sometimes due to the invasion of the organism by another pathogenic agent; it is known that wherever two different microbes are in conflict in the same organism, one will overcome the other, and the result will be for this last one a neutralized effect, an attenuation. For the bacteria of malignant carbuncle, Emerich has established that its development is interfered with by the presence of the streptococcus of erysipelas, and Pawlowsky has shown that the pneumococcus prevents its development. I have myself brought about the recovery of a rabbit inoculated with a culture of malignant carbuncle bacilli, by inoculating it afterward with the pyocyanic bacillus.

But if on the same field or medium two microbes can interfere with each other, they can also assist each other. Has not M. Roger lately demonstrated that the inoculation of the bacillus prodigiosus renders possible in the rabbit the development of a special species of gaseous gangrene to which this animal is refractory when the two microbes are not associated?

Every day, science clears away apparent contradictions. It has pursued the microbe where it lies hidden, not only in the spleen, in the marrow of bones, in the lymphatic organs but also in the lungs, in the liver, in the kidneys and in the vascular endothelium. If its presence does not produce in those parts an appreciable pathological change, it has impressed the nutritive type; and later, when it has disappeared, chronic lesions are liable to appear,—cirrhosis, nephritis, endarteritis, valvular alteration having infection for its cause, but as a distant cause. These are all diseases of infectious origin, to combat which antiseptics are of no avail. These late localizations of infectious diseases do not proceed directly from infection, they are the result of a permanent interference with the nutrition of the cells of certain organs, which have been impressed previously by an infectious agent. They have the greatest resemblance, as regards anatomical lesions or pathogenic processes to similar alterations of these same organs which occur in general diseases of nutrition or in certain intoxications. It is for this reason that in my lectures of this year, when I am to study the localizations in general diseases, I shall consider in parallel line those proceeding from infection, those derived from a diathesis, and those which are produced by an intoxication.

To-day, before separating, I should like to leave in your mind this thought: that pathogenic notions are useful; that to possess one single pathogenic notion alone condemns one to powerlessness; that the contradictions, of which so much has been said, between clinical facts and pathogenic doctrines are only apparent, and that the scientific work of every day contributes to dissipate them in giving to the facts their real interpretation.

COMMUNICATIONS.

EARLY DIAGNOSIS OF LATERAL CURVATURE OF THE SPINE.[1]

BY JOHN RIDLON, M.D.
NEW YORK CITY.

Upon the early diagnosis and the rational treatment of the conditions presenting in lateral curvature of the spine will depend the successful or unsuccessful termination of the case. When the distortion has advanced so far that the diagnosis is made by the dress-maker or some lay-friend, it may fairly be said to have passed the time for an early diagnosis, and generally passed the time for a complete eradication of the deformity.

It is not easy to say how early a case of lateral curvature can be diagnosticated. I am inclined to think that it will depend upon the cause of the curvature; for upon the cause will depend the first symptoms. A curvature following and depending upon one of the fevers, as scarlatina or typhoid, will present early symptoms differing greatly from those of a curvature following a pleurisy and depending upon the contraction of the pleuritic exudation, although, when well advanced, the distortion is in no way different. So also, a case depending upon a shortening of one lower extremity, congenital or acquired, will, in its early symptoms, differ from one due to poliomyelitis anterior, although both may progress to the same characteristic deformity. In a word, a case may begin with curvature and rotation, or without curvature, or without rotation, or without either curvature or rotation, and still present diagnostic symptoms.

An early diagnosis may be characterized as such when there is as yet no deformity of the spine, or only such deformity as can by posture or manipulation be temporarily eradicated. A deformity which, at the first examination, cannot be made to disappear, will pretty generally resist treatment, at least so far as the primary curve is concerned; although some do remarkably well, as will be seen in the case which I shall present to demonstrate the exercises.

In a case in which there is actual bony anchylosis of the vertebræ on the concave side, we can not hope in any measure to change the primary curve, although much can be done to render the deformity apparently less by reducing the prominent hip and the compensatory curves above and below the area of anchylosis.

[1] Read before the Surgical Section of the New York Academy of Medicine, October 8, 1888.

A successful termination may mean an eradication of the deformity and an erect and graceful carriage, or only an arrest of the primary and a reduction of the secondary curvatures with increase of health and strength; or it may mean any degree between these extremes; a termination is not considered successful which leaves the patient encumbered with a brace or jacket, and with muscles so weak and flabby that the supported position can not be maintained when the support is removed; neither do we consider as successful, cases that present a greater deformity at the end than at the beginning of treatment.

By rational treatment is understood the attempt to meet indications, as presented by causation and symptoms, in each individual case, with the end constantly in view to restore the figure so far as possible to the normal contour, and so to strengthen the muscles that this normal contour may be easily and instinctively maintained. Routine treatment of any kind is to be deprecated, but the routine treatment of every case of lateral curvature, no matter what its cause or how varied its symptoms, by any one kind of brace or any one exercise is opposed to our idea of rational treatment.

Rotation of the vertebral bodies, causing the convexity and concavity—the bulging and the falling in—is the characteristic symptom of this deformity, and in a very large number of cases it appears very early. This bulging can be best seen by causing the patient, stripped to the hips, to bend forward, the arms hanging and the knees straight and rigid. But even before this rotation can be detected there are, in some cases, characteristic symptoms: as the patient walks, if unconscious of observation, the head is carried somewhat to one side, the shoulder of that side is slightly advanced, and the foot of the same side is rotated out.

If the patient is asked to lie down upon some plane surface, as a table or the floor, and is simply told to "lie straight," this carrying of the head to one side and outward rotation of the foot will become more easily apparent. If then, with the arms straight and the elbows and wrists rigid, the patient is made to grasp a stick lying across the thighs, with the hands so far apart that the arms are parallel, and is directed to carry the stick forward and upward over the head, it will be seen that the plane through which either arm passes is not parallel with the antero-posterior plane of the body, but that, as the arms pass upward, they will swerve to one side—the side toward which

the head leans and the foot points. If the surgeon now grasps the stick between the patient's hands when it is resting on the thighs and forcibly makes the arms follow planes parallel to the antero-posterior plane of the patient's body he will distinctly see and feel the stick twist in his hand. At starting, one end of the stick will be lower than the other, that is, farther down the thigh and that arm appear the longer arm; when it has passed through ninety degrees and is opposite the face, the other arm will appear the longer; and when it has been carried ninety degrees more, the first arm will again appear the longer.[1] This phenomenon appears to depend upon the advancing of one shoulder beyond the other, and, together with the deviation of the head and the rotation of the lower extremity, can doubtless be traced to the same central lesion that causes the subsequent vertebral rotation.

In cases in which these symptoms have been noted, distinct rotation has been observed for a very considerable time before any lateral deviation of the line of spinous processes began to appear. On the other hand, when the lateral deviation appears before rotation, as in curvature depending upon one short lower extremity, I have not found the neck and shoulder symptoms and the outward rotation of the foot.

It may be asked if *true* scoliosis can be caused by a short leg or a contracted pleural cavity, and I should answer, in the present uncertainty as to the etiology of true scoliosis, that lateral deviation of the spine with rotation of the vertebræ, and all the characteristic forms in the late stage do follow, and may undoubtedly be caused by, a short leg or a contracted pleural cavity, and that such a curvature is to all intents and purposes as true a scoliosis as one that comes without known causation.

For the sake of greater clearness in arranging symptoms I shall divide our cases into two classes: (1) those that present rotation before curvature, and (2) those that present curvature before rotation.

In the first class, in which rotation appears before the curvature, the symptoms generally appear in the following order: Outward rotation of the foot on the side toward which the convexity is to look—this is more marked when the patient lies supine than when he is standing; the head is carried somewhat toward the same side; the shoulder is carried forward, separating the scapula from the line of the vertebral spines farther than on the opposite side. If the patient be a woman with mammæ developed, there will be found on palpation atrophy of the gland on the side of the advanced shoulder. Then comes bulging of the ribs on this side and sinking in of those on the other side—this is best seen when the patient bends forward. About this time comes the lateral deviation of the line of the spinous processes. I shall not venture an explanation why this is more frequently seen in the dorsal than in the lumbar spine, and more frequently to the right than to the left. As the curve increases the shoulder of the concave side drops lower than that of the convex side, and either a compensatory curve appears in the lumbar region, or the hip of that side becomes elevated and prominent. When there is a compensatory curve in the lumbar region it is the hip on the side of the convexity of the primary curve that becomes prominent. As the bulging of the ribs increases, the shoulder on that side is carried further forward, and the lower angle of the scapula is tilted out in marked contrast to the one on the opposite side, which lies abnormally flat against the sunken chest wall. If the deformity is far advanced this scapula, on the convex side, can not be carried back into place by any effort of the patient; while if the deformity is not far advanced it can be pretty nearly replaced. After a time the compensatory curve, which at first was simply a lateral deviation, undergoes rotation, and it may even become rigid. Lordosis, also, is of not infrequent occurrence. In some few cases there is found to be some degree of shortening of the muscles of the calf of one or both legs, and even a slight degree of talipes equinus.

The symptoms above enumerated may go progressively on to almost any degree of deformity, or they may cease to progress at any time, either with or without treatment. One patient, for instance, wore a brace for some two years, and grew gradually worse. She was then treated for some months by electricity and certain passive manipulative exercises, with little or no gain. During the following two years she had no treatment, yet the progress of the distortion stopped and she became somewhat straighter. Another patient wore the same brace and had passive manipulative exercises for about ten months, during which time she grew gradually worse; but with the brace removed and under active manipulative exercises and

[1] This latter condition is reversed when the deformity has progressed so far that one shoulder is higher than the other.

gymnastics she has become rapidly straighter. The progress of the distortion is sometimes very slow, going on for upward of ten years; in other instances the same degree of deformity may be reached in a few months.

In the second class of cases, in which the curvature precedes the rotation, the first symptom appearing is the lateral deviation of the line of the spinous processes. This, however, is not usually noted, since the curve, not being rigid, is not permanent; and the symptom which is usually first noted is the prominent hip. Not infrequently, however, we can obtain a history of an uneven gait and a faulty habit of standing or sitting in a flabby and rapidly growing child. The relation of the prominent hip to the curvature, that is, to the convexity or concavity, will depend upon the location of the curve. If it is lumbar, the prominent hip will be on the side of the concavity; and so it will be if there is only one curve occupying most of the dorsal and lumbar spine; whereas, if there is a double curve, to the right in the dorsal and the left in the lumbar spine, the prominent hip will be that on the side of the dorsal convexity. After a curvature of this kind has existed for a certain time, usually many months or some years, rotation supervenes and with it all the consequent symptoms: bulging of the ribs on one side in the back and of the other side in the front; flattening of the ribs of the first side in front and of the opposite side in the back; tilting out of the lower angle of the scapula and elevation of shoulder on the side of the convexity, and flattening of the scapula and lowering of the shoulder on the side of the concavity. In this class we have not found outward rotation of the foot, and the peculiar advanced shoulder during locomotion, which is so often seen in the cases of the first class; but the lateral deviation of the head appears subsequent to the lateral deviation of the line of the spinous processes. It is very doubtful if true mammary atrophy occurs in the cases of this second class, but I have observed a smaller but not a flabby gland on the side of the convexity. A considerable number of patients also present a condition of flat-foot.

The spinal rigidity comes slowly as compared with the cases of the other class, and these are, therefore, by so much, more amenable to treatment. In the cases in which there is a short lower extremity it is an advantage to have the length equalized by a high shoe, but this is not absolutely necessary for a good result. In cases in which the deformity is due to, or associated with, the contraction of a pleuritic exudation great care should be exercised in the use of active manipulation, lest the inflammatory process be renewed again.

Treatment should consist in the reduction of the deformity, and the development of the muscular strength to maintain the acquired position. This is gained by posture, manipulation, massage, and gymnastics with assistance and with resistance. In many cases electricity is of use, and the proper arrangement of the clothing is of no small importance; but of more importance than any other one thing I believe to be the constant maintenance, *by voluntary effort*, both during the exercises, and in the intervals between the exercises, of the *best possible position*—the "keynote position" of Roth. As to the use of braces, supports, jackets, and corsets, it is difficult to lay down any uniform rule. In some cases they are unnecessary, in some even harmful, while in some they are of great comfort to the patient; but it should not be lost sight of that their use is prejudicial to muscular development, and delays the ultimate favorable result.

THE PATHOLOGY AND SURGICAL TREATMENT OF SEBACEOUS TUMORS.[1]

BY CHARLES B. WILLIAMS, M.D.,
PHILADELPHIA.

Sebaceous tumors, or as they have been variously called by different authors, *encysted tumors; atheromatous cysts*—and *wens*, are classified pathologically among the sebaceous cysts. The pathology of the sebaceous tumor makes quite an interesting study, and, in fact, a certain knowledge of this pathology is essential before we can intelligently perform the radical operation. Sebaceous tumors, or as they are more generally called, wens, are quite frequent among hairy persons.

Their favorite seats are in the sub-cutaneous connective tissue, especially of the scalp and scrotum. In the interior of the body they are more rare. These tumors consist of accumulated masses of epidermis and sebaceous matter in the hair follicles, and are a result of the distension of the sebaceous gland and its duct, with hypertrophy of the walls, which forms a thick, tough sac or cyst. They vary in size from that of

[1] Read before the D. Hayes Agnew Surgical Society, Feb. 14, 1889.

a pea to that of a walnut or a pigeon's egg, or are even larger, and may occur singly or in numbers.

In shape they are habitually flattened and lenticular. According as their contents are fluid or solid they are termed *melicerous* or *steatomatous* wens.

The *melicerous* wens (μελι—honey; κηρος—wax) contain a substance semi-fluid in consistency like honey, comprising a large quantity of free fat and isolated epidermal cells.

The *steatomatous* wens (στεαρ, στεατος—solid fat) have more solid contents, consisting of the same elements as the melicerous wens, only there are more epidermal cells and less free fat. In both forms the fat undergoes a metamorphosis, and as it is no longer subjected to nutritive changes it gives rise to crystals of stearic acid, margarin and cholesterin. The cyst is located in the sub-cutaneous tissue. The skin covering it is thinned at the surface, and its papillæ are flattened or they have disappeared entirely—while the surface is smooth, more or less devoid of hair, and with atrophy of the sebaceous glands.

As regards the microscopical structure of the cyst itself we have to consider first its fibrous wall, which consists of connective tissue with flattened spindle shaped cells, a tissue identical with that of the inner coat of arteries and that of fibroma. This disposition, we are told, is caused by pressure exerted upon the walls by the incessant accumulation of the elements contained within the cyst. Fatty, atheromatous, and calcareous degenerations may take place in this connective tissue wall, and this still further increases the analogy of this membrane with the internal coat of arteries. Hence also the name *atheromatous* cyst. Next to the fibrous membrane we have layers of stratified pavement epithelium which undergo evolution similar to that found in sebaceous glands.

The cells nearest to the spindle cells have large nuclei surrounded by a small quantity of protoplasm; and it is probably here that new cells are constantly being formed. Next we have a layer of horn-like cells which are devoid of nuclei. And lastly an innermost layer containing sebaceous globules. Often the horn-like layer of cells detaches itself from the wall of the cyst and forms a shell-like membrane, slightly translucent and almost cartilaginous in texture. It is within this membrane that we find the melicerous or steatomatous contents. Hence the necessity, in operating, of removing this membrane along with the contents of the sac. For if one should leave the membrane behind and merely evacuate the contents of the cyst, new cells would be engendered and cast off, together with the formation of more sebaceous globules which would in turn be cast off, and from this increase of new material we would have, in a short time, a recurrence of the sebaceous tumor.

The diagnosis of sebaceous tumors is an easy one, and probably the only tumor with which it may be confounded is the lipoma. In the lipoma or fatty tumor we have the fatty mass invested by a capsule. From this capsule septa pass inwardly, dividing the tumor into lobes of various sizes. Making the skin tense and passing the fingers over the lipoma, then, we get the dimpling which is characteristic of this tumor. And besides we may feel its lobular structure by careful manipulation. Another final proof we derive from our knowledge that all fatty matters become hardened by the application of cold; hence if a spray of ether be directed upon a lipoma, its contents will be rendered hard and firm. The treatment, however, would be the same in both tumors, i.e., excision; and a slight error in diagnosis would, therefore, not be accompanied by any serious results.

In an operation for sebaceous tumors, at which I assisted last autumn, three wens were removed from the head of the patient, without the use of ether. A sharp bistoury was, by a rapid thrust, carried through the longest diameter of each tumor, slitting up the cyst and disclosing its contents, which were of a greenish yellow color and *melicerous*, or semi-fluid in consistency, containing flakes of sebaceous matter and broken down cells. The contents were evacuated and with the aid of a pair of forceps the membranous wall of the cyst was carefully dissected away from the scalp. The hemorrhage was very slight and was easily controlled by pressure with sponges. The operation was conducted with antiseptic precautions, and afterward the parts were washed with bichloride solution, the edges of the wound were brought together and held by a single suture, an antiseptic dressing was applied and held in place by a few turns of a roller bandage.

As regards the use of an anæsthetic in these operations, I may say, that it depends entirely on the patient:—Should he happen to be as great a stoic as the patient referred to above was, he will require no anæsthetic; but if he be timid and afraid of a little pain then ether had better be administered.

Society Reports.

SIXTH CONGRESS OF THE ITALIAN SOCIETY OF SURGERY.

AT BOLOGNA, APRIL 16, 17 AND 18, 1889.

(Specially reported for the Medical and Surgical Reporter)

The meeting of the Italian Society of Medicine took place at the University of Bologna, which celebrated last year its eighth centennial anniversary. The meeting was presided over by Dr. Loreta, Professor of Clinical Surgery at the Faculty of Medicine of Bologna.

Prof. Ceccherelli, of Parma, read the first scientific paper on

Surgical Intervention in Cases of Tubercular Peritonitis.

Sometimes after the diagnosis of abdominal tumor has been admitted in a certain case, we find, after opening the abdomen, that we are in the presence of a tubercular peritonitis; this mistake of diagnosis, however, can become, in certain cases, of some utility to the patient. In view of the fact just mentioned, I have tried to consider in which cases of tubercular peritonitis we are enabled, by the aid of surgery, to be of some use to the patient, and what are the reasons of the utility of our intervention.

I have had the opportunity of studying this question on four patients, who presented themselves at my clinic. The first case was that of a woman, 32 years old, who had had five children; after her fifth child she suddenly lost her appetite, and her abdomen became enormously enlarged, due to the collection of a great quantity of liquid in the peritoneal cavity. On opening the abdominal cavity, tubercles were discovered; and after the withdrawal of several pints of liquid, and washing out the serous membrane with a solution of thymol, and the dusting of the parts with iodoform, all the symptoms disappeared and the patient was cured. In a second case, in a young boy of eleven, who was suffering from a progressive ascites, the same treatment as in the preceding case—thymol and iodoform over the involved tubercular part—was employed. Several weeks later, however, the ascites reproduced itself, and I had to resort to a second laparotomy, which exposed numerous adhesions between the coils of the small intestine and between the parietal and visceral layers of the peritoneum; cultures made from these new formations gave negative results. The boy is very much improved as regards his abdominal condition, but for some time past he has shown signs of involvement of the apex of one lung.

My last two laparotomies were performed on children, one 6 years the other 8 years old; the ascites was very pronounced, and encysted in separate pockets, which I was able to empty and disinfect very easily. A microscopical examination showed the specific tubercle bacillus. Both these patients were cured and in both the diagnosis of tubercular peritonitis was well proven by physical test.

Up to date, 86 cases of tubercular peritonitis have been recorded as having been treated by laparotomy; out of which 52 have been cured, six improved, in five cases the result was unknown, the patients having been lost sight of; and, finally, twenty-five died.

I divide tubercular peritonitis into two forms: first, dry tubercular peritonitis; second, ascitic tubercular peritonitis. In the first form, surgical interference is of no avail and would be impossible or useless on account of the numerous adhesions that exist, which it would be very difficult and very dangerous to remove. In the ascitic form, however, surgical intervention is to be recommended, especially if the liquid is encapsulated; if the liquid is free in the abdominal cavity, simple puncture, accompanied by washing out of the serous cavity, is all that we can do.

The cure in cases of laparotomy is produced by an adhesive peritonitis subsequent to the operation; this leads to the formation of connective tissue bands which surround and strangulate the tubercles; when these adhesions already exist, as in the dry form of peritonitis, operative interference would be much more harmful than useful.

Prof. Durante, of Rome, does not believe that tubercular peritonitis can be absolutely cured; he thinks that these so-called cures are only of a temporary character, as we all know that tubercular peritonitis can remain localized for over ten years. Moreover, tubercular peritonitis is also liable to be diagnosticated when we have to deal with a pseudo-tubercular state of this serous membrane.

Prof. Bassini, of Padua, mentions the fact of two of his patients with tubercular peritonitis, who died from pulmonary tuberculosis, one eighteen months and the other two years after the laparotomy.

Dr. Ferrari also accepts the operation as a palliative against serous peritonitis which complicates tubercular abdominal affections; but he does not believe in the final cure of the disease.

Prof. Ruggi, of Bologna, read a paper on the

Use of Corrosive Sublimate in Laparotomies.

I present to you to-day, a statistical account of a series of 115 cases of laparotomies, which I performed last year in my hospital, as well as in my private practice, and in which bichloride of mercury solutions have been used. My cases are divided into:

Single oöphorectomies, 21; cured, 21. Oöphorectomies and salpingectomies, 10; cured 10. Castration for several causes, 14; cured 14. Extirpation of sub-peritoneal fibroids, 4; cured 4. Salpingectomies, 15; cured 4. Supra-vaginal amputations of the uterus for fibroid tumors, 24; cured 19; deaths 5. Laparo-hysterotomy for sarcoma, 1; death 1. Hysterotomies by Antona's method, 3; cured 3. Extirpation of cysts of the parametrium, 2; cured 1; death 1. Intra-abdominal straightening of the uterus by my method, 19; cured 19. Laparotomies for tuberculosis of the peritoneum, 3; cured 3. Echinococcus cysts of the peritoneum and liver, 2; cured, 2. Exploratory laparotomies 5; cured 5. Ascites, 1; cured 1. Laparotomy for foreign body, 1; cured 1.

I have had in all 107 cures and eight deaths, two of which I attribute to poisoning by corrosive sublimate. These two patients I operated upon for fibroid tumors of the uterus; death occurred in less than twenty-four hours and was preceded by a rapid collapse. On *post-mortem* examination, we found a degeneration of the renal and hepatic cells of toxic origin. The poisoning must have taken place as follows: the napkins to be used for the dressing of the peritoneum had been dipped in and kept for too long a time in a solution of corrosive sublimate, which had probably caused the deposition of the salt on the napkins themselves. Hereafter I intend to use exclusively boiled water, instead of the sublimate solution.

Prof. Bassini has observed two cases of death as a result of poisoning with corrosive sublimate; he now uses salicylic acid instead.

Prof. Durante, of Rome, asserts that peritoneal absorption readily takes place only when we have to deal with a normal serous membrane; but he thinks that when there exists an irritated condition of the peritoneum, we can safely wash this serous membrane even with a 1 to a 1000 solution.

Prof. d'Antona, of Naples, has made a series of thirty-two ovariotomies, with not one death, which he attributes to the use of corrosive sublimate employed with all due care. Among his cases he mentions two of adeno-carcinoma, cured by extirpation, without a recurrence of the disease.

Prof. d'Antona, of Naples, reported a case of

Cure of Hystero-Epilepsy by the Extirpation of the Uterine Appendages.

I have operated on a young woman, who, after having suffered from metrorrhagia due to a uterine retroflexion, presented all the classical symptoms of hysteria, namely: ovarian pain; anæsthesia, shortening of the visual field, hystero-epileptic attacks which could be brought on by compression of the ovaries. The reposition of the uterus brought about a temporary amelioration, but soon afterward the metrorrhagia occurred again, and I was compelled to remove the appendages. The tubes were found in a state of congestion, and the left ovary was undergoing cystic degeneration, while the right one was in a much advanced stage; still the patient recovered perfectly.

Dr. M. Frangelini, of Frosinone, reported a case of

Extirpation of an Ovarian Cyst in a Pregnant Woman.

I have extirpated a very large ovarian cyst from a woman who was in her sixth month of pregnancy, the pregnant condition being recognized only at the time of the operation. The incision started at the symphysis pubis and extended to about four inches above the umbilicus. The patient was walking fourteen days after the operation. The pregnancy did not come to full term. The patient did some hard household work, besides indulging in too frequent sexual connection; these brought on labor, which was uncomplicated. This observation demonstrates that we can extirpate ovarian tumors during pregnancy without bringing on abortion.

Dr. Boggi, of Bologna, read a paper on

Dilatation of Strictures of the Cardia and Pylorus.

In presenting to you the statistics of the laparotomies which have been performed at the clinic of Bologna, I shall call your

attention especially to those which have been made for diseases of the stomach, to produce a digital dilatation of the pyloric strictures and an instrumental dilatation of the cardia. I shall not attempt to give you the *modus operandi* of the process, but shall confine myself to recording observations made upon my two last patients.

Case I.—A man 56 years old, had been sick for eight years past, vomiting every two or three days, about seven hours after the meal, a quantity of badly digested food. The hypogastric region was in a tumefied condition, while the inferior portion of the abdomen was quite retracted. He evacuated his bowels only every eight or nine days. As a result of my examination I concluded that I had to deal with a fibroid stenosis of the pylorus. After having opened the abdomen and then the stomach, the pylorus was hardly large enough to allow the passage of the little finger; but gradually dilatation occurred and I first could introduce one index finger, then the other one, and then was able to make a forcible stretching. The patient is to-day cured, eats well, has no more vomiting, and his digestive functions are in a perfect state.

Case II.—My second patient was a man, 48 years old, who had been suffering for several years. On examination we found a cicatricial stricture of the cardia, with dilatation of the œsophagus immediately above it; the stomach was very much retracted.

After opening the abdomen and stomach, the latter organ was very difficult to find or recognize, on account of its small retracted form. The closed extremity of Dupuytren's *revulseur* was introduced into the cardia, and dilatation was made, after which a large œsophageal sound was introduced into the stomach. Fourteen days later, the patient left the hospital completely cured. This man had been suffering for twenty years, and since the operation he has been feeling perfectly well, having no more any rejection of food after his meals

Dr. Bendandi, of Bologna, cannot admit that a temporary dilatation, such as is made with the fingers, can really bring about a permanent cure. He admits the persistency of the dilatation of the cardia, as this dilatation can be maintained by the œsophageal tube; but he cannot understand how dilatation of the pylorus can remain permanent.

Dr. Putli, of Bologna, like the preceding gentlemen, cannot admit the persistency of the dilatation of the pylorus, considering that for stricture of the urethra we are obliged, after the stricture has been cut, to maintain the dilatation by the occasional passage of a sound.

Dr. d'Antona says that strictures of the pylorus cannot be compared with strictures of the urethra; they are more analogous to strictures of the anus, which when once forcibly dilated remain pervious.

Dr. Poggi: I have studied the effects of forcible divulsion on healthy sphincters and on cicatricial tissues, and as a result of my researches, I think I can affirm that if divulsion does not succeed in certain very rare cases where the pyloric ring is completely transformed into a cicatricial tissue, there exists on the other hand a very large series of retractions caused by partial and superficial cicatrices, which are easily dilatable. I have made on the normal pylorus of several dogs, a dilatation which was still recognizable one year and a half after the operation.

Dr. Postempski, of Rome, read a paper on the

Reduction of Diaphragmatic Hernia.

At the Hospital of Consolation, in Rome, I observed, some four months ago, a patient who had been wounded in the left seventh intercostal space, and who, while he was lifting a heavy weight, was suddenly seized with pulmonary, cardiac and intestinal symptoms, and presented in addition the symptoms of intestinal obstruction with displacement of the heart.

The diagnosis of diaphragmatic hernia was confirmed by the *post-mortem;* the hernial part was not adherent to the diaphragmatic opening, it was only compressed and strangulated. I then thought that we might bring about a radical cure of such hernias, by penetrating through the thorax instead of through the abdomen; several experiments on the cadaver convinced me that it was a feasible operation, which six weeks later I had the opportunity to perform on the living subject. The patient was a young man who had received a wound in the eleventh intercostal space, of three and a half inches in length; after having enlarged the opening three-fourths of an inch more, I made two perpendicular incisions, as if I was going to make a thoracoplastic operation; the opening being more dilated, I had all the light and space desired. I had to deal with a hernia of the omentum. I freed it from its strangulation and then brought the lips of the diaphragmatic wounds together by the aid of forceps. I then sutured with a very long needle-holder. Next the external wound was sutured. After

the operation, a very large pneumothorax made its appearance, but it progressively diminished until the twelfth day, when it had entirely disappeared. Eighteen days later, my patient was presented before the Academy of Medicine of Rome, completely cured.

PROF. DURANTE reported a case of

Extirpation of the Cæcum,

which he had performed on a woman, 52 years old, who for four or five years past had suffered very much in the right iliac fossa, when she evacuated her bowels. In this region, a resistant tumor could be felt extending down as far as the superior strait of the pelvis; the diagnosis was atrophic or fibrous cancer of the cæcum and adjoining parts.

The operation was a very tedious one, on account of the numerous adhesions which existed between the small intestine and peritoneum and the tumor, and for the additional reason that it was difficult to differentiate the small from the large intestine, on account of the unusual displacement of the parts. I succeeded, however, in cutting the cæcum, and I united the intestinal stumps by means of sutures in three rows. The patient was rapidly cured.

Seven days after the operation, the patient had her first fæcal passage, on the tenth she left her bed. An examination of the extirpated parts showed that we had to deal not with a cancer, but with a case of chronic, indurated typhlitis or perityphlitis of tuberculous origin.

DR. TROMBETTA has also extirpated the cæcum with the ascending colon, thinking he had to deal with a case of cancer, while it was one of chronic typhlitis and perityphlitis accompanied by numerous small abscesses. He formed an external fistula, but the patient died on the fourteenth day from peritonitis due to rupture of the intestine.

PROF. TIZZONI, of Bologna, read a paper on the

Etiology of Tetanus.

A case of tetanus, which has lately taken place at the surgical clinic of Bologna, has given me the opportunity to make, in collaboration with Miss Cattani, *privat-docent* of our Faculty of Medicine, bacteriological researches on this very dangerous affection. The patient was a workman, who fell and sustained a complicated fracture of the arm; the fractured bone had gone through the skin, and had implanted itself in the earth. The blood of the wounded person appeared normal on microscopical examination; perhaps it coagulated too rapidly. Cultures on serum, made with this blood, remained negative, and inoculation of rabbits gave no pathogenic effect. We next made cultures with the liquid obtained on the surface of the fracture, and with liquid obtained at some distance from the immediate wound, but still in the inflamed region. Of all these cultures, the only ones which have given positive results are those which have been made with liquids obtained from the surface of the wound. After the death of the patient, I tried to ascertain in what organs the virus had propagated itself, from the seat of fracture. For this purpose, I made cultures from the nervous system and spleen; but all have given negative results; the liquid alone which was derived from the wound itself produced positive cultures and killed the animals which were inoculated with them. The cultures obtained on the gelatinized blood-serum are mixed cultures; they liquefy the serum, which is transformed into a yellow liquid, having tetanizing qualities highly developed; injected into animals, it kills them in twenty-four hours, with well defined tetanic symptoms.

We have cultivated this liquid, and we have assisted the development of mixed colonies, in which we have been able to isolate three species of microörganisms: (1) a streptococcus in globular colonies, which do not liquefy the gelatine; (2) a diplococcus, exactly similar to the one of Fraenkel, and having all its biological characters; (3) a bacillus, identical in every way with the tetanic bacillus of Nicolaier and Rosenbach.

We have been able to isolate these bacilli, the culture of which is rapidly weakened when on serum, but which will keep much longer on agar-agar. We have been able to bring them up to the ninth generation. The injection of such cultures invariably produces tetanus.

PROF. LAMPIASI, of Trapani, said: The microbe of tetanus which I have discovered has well defined characters, and has always produced a typical case of tetanus in the numerous animals in which it has been inoculated. I have a culture of this microbe which has kept its virulence for the past two years. As my results differ from other experimenters I am led to believe that traumatic tetanus differs from the rheumatic form, and that each can be developed by a different microbe.

Dr. Lampiasi also mentioned the fact

that cultures made with Rosenbach's bacillus produce no tetanic phenomena.

Dr. Tizzoni: I admit that the pure cultures of the bacillus of Rosenbach have no pathological action, it is only by the entire liquid and its contained bacilli that the tetanic symptoms are produced. My researches are different from those of Dr. Lampiasi, for I have started from a case of traumatic tetanus while the one which has been studied by Dr. Lampiasi was a case of spontaneous tetanus. In the inoculated rabbits signs of infection were found only in the spleen.

(*To be continued.*)

KENTUCKY STATE MEDICAL SOCIETY.

THIRTY-FOURTH ANNUAL MEETING, AT RICHMOND, MAY 8–10, 1889.

The Kentucky State Medical Society held its thirty-fourth annual meeting at Richmond, Ky., May 8, 9 and 10, 1889. The reports of the various officers and committees showed the society to be in a prosperous condition.

The address of the President, Dr. L. S. McMurtry, was a history of the society. It was brief and to the point. Much satisfaction was expressed by the various members at the new medical practice law which has just gone into effect, and on motion of Dr. J. N. McCormac, of Bowling Green, the President was instructed to appoint a committee, consisting of three in each county, to look after the enforcement of the new law. The surplus funds in the treasury at the close of this meeting are to go toward the prosecution of violators of the law.

A banquet was given at the Garnet house, and was a very pleasant affair. Toasts were responded to by the President, Dr. McMurtry; Ex-Governor McCreary, of Richmond; Dr. W. H. Wathen, of Louisville; Dr. D. S. Reynolds, of Louisville; Dr. J. M. Mathews, of Louisville; and Dr. O. D. Todd, of Eminence. A hop was also given the Society at the rooms of the Madison Club.

The officers elected for the ensuing year are as follows: *President*, Dr. John A. Ouchterlony, of Louisville; *Senior Vice-President*, Dr. William Jennings, of Richmond; *Junior Vice-President*, Dr. R. L. Willis, of Lexington; *Permanent Secretary*, Dr. Steele Bailey, of Stanford; *Assistant Secretary*, Dr. John Young Brown, of Henderson; *Treasurer*, Dr. J. B. Kinnaird, of Lancaster; Chairman of the *Committee of Arrangements*, Dr. James H. Letcher, of Henderson.

A good feature of the scientific part of the programme was the reports on progress in the different departments. That on Surgery was made by Dr. W. L. Rodman, of Louisville; that on Medicine by Dr. J. W. Gilbert, of Lawrenceburg; on Hygiene, by Dr. J. N. McCormac, of Bowling Green; on Gynecology, by Dr. W. H. Wathen, of Louisville; that on Obstetrics by Dr. J. G. Cecil, of Louisville; on Laparotomy for Penetrating Shot Wound of the Abdomen, by Dr. David Barrow, of Lexington; on Medical Ethics, by Dr. Dudley S. Reynolds, of Louisville; on Diseases of the Rectum, by Dr. J. M. Mathews, of Louisville; on Ophthalmology, by Dr. S. G. Dabney, of Louisville; on Otology, by Dr. J. M. Ray, of Louisville; on Progress and Treatment of Pulmonary Tuberculosis, by Dr. F. C. Wilson, of Louisville; on Vital Statistics, by Dr. T. B. Greenley, of West Point.

Cincinnati was represented at the meeting by Drs. T. P. White, A. B. Thrasher and E. S. McKee. Drs. Thrasher and McKee read papers; the latter was a delegate from the Ohio State Medical Society.

Dr. J. A. Ouchterlony, of Louisville, read a paper on the Transmissibility of Tuberculosis, which was of much interest. The theory of inheritance he thought had been thoroughly shaken. Tuberculosis is rarely if ever congenital. The object of the paper was to show that tuberculosis can be transmitted from the lower animals to man. There can be no security from tuberculosis as long as tuberculous meat and milk are used. He insisted that the medical profession should bring this matter before the public and instruct them thereon. On motion, such a committee was appointed for such a purpose.

Several reports of cases and papers on the subject of extra-uterine pregnancy were furnished. The general opinion was in favor of operation, and not much faith was placed in the treatment by electricity, as it was thought practically impossible to diagnosticate this condition before the twelfth week; and what to do with the tumor when the child was killed by electricity was a question of difficulty.

Dr. Joseph M. Matthews, of Louisville, read a paper on the Importance of Rectal Examinations to Life Insurance Companies. No company, to his knowledge, demands

rectal examinations. He reported several cases in which applicants were received who had serious rectal trouble, which soon proved fatal and the insurance companies were heavy losers.

The discussion of acute traumatic tetanus was one of considerable interest, and drew out a number of case reports and treatment. The general opinion was that bromide of potassium is the best remedy. The only fear is that it may not be given in doses of sufficient quantity. Dr. J. C. Brooks, of Paducah, had given five grains of morphia hypodermically to a man once who was given over to die of traumatic tetanus, and the man recovered and remained well.

Reports of Clinics.

PHILADELPHIA HOSPITAL.

SURGICAL CLINIC—DR. STEINBACH.

Syphilitic Disease of the Tibia.

The patient before you, a girl twenty-two years old, is suffering from some severe bone lesion. The region of the tibia near the knee is riddled by several sinuses. The knee itself is anchylosed. Whenever there is severe disease near a joint, the joint itself will necessarily be fixed to avoid pain and, from the inflammation in the neighborhood, the joint structures will be bound together, not in a bony union but in a false anchylosis.

I do not know what I shall do here. I shall examine first and, if the joint is involved at all, will resect it and give the patient a fixed limb to walk on. Still, the bony tissue left may be too little to allow a resection at present and, in that case, there is danger that an amputation may have to be done at no distant time.

Bone diseases may be caused by traumatism, occasionally by struma, but, I believe, in this case it is due to a specific disease, which I need not name. The indications of knee-joint trouble are not very apparent here; still, the patella is hardly movable and the joint is fixed at an obtuse angle. It is supposed that an obtuse angle in the leg is better than a straight limb, but I do not find it so.

A long incision will be made over the tibia, and the dead bone found and removed. The probe entering a sinus goes straight up to the cartilage of the joint. The head of the tibia is the usual seat of necrosis and here the cancellous tissue immediately beneath the articular surface is so badly involved that my finger sinks into the bone. I have already invaded the knee-joint in following up the diseased structures. The bone is a mere shell, so that resection can not be thought of, there being no structure underneath to build on. The probability is that we shall have to amputate this limb, and it would be proper to amputate at once; but we have not the consent of the patient.

A large portion of the head of the tibia was curetted away, so that only a layer of cartilage was between the finger and the knee joint, which was distinctly involved. An Esmarch bandage had to be applied to control hemorrhage. Continuing, Dr. Steinbach said: In young subjects it is possible to remove large masses of bone and still have the cavity fill up. Care must be taken to leave no dead bone behind, otherwise the operation will be a failure. It is the same work as a dentist's, only on a larger scale. In removing the dead bone, I have left only a thin shell posteriorly, but the popliteal and the posterior tibial are so well covered with soft tissues that there is hardly any risk of injuring them.

It will be necessary to take even greater care of the limb than if it had been amputated, for the bone will break readily, so that a splint will be used. I curette thoroughly all the sinuses which led to the dead bone, and, although it is to be treated as an open wound. We desire to approximate the soft parts to some extent, and I will insert a few sutures and then the cavity will be packed with iodoform gauze.

Vertebral Abscess.

Abscess in the lumbar region almost always indicates caries of the vertebræ. It would be proper to speak of abscesses commonly called lumbar or psoas as vertebral abscesses, since it is entirely accidental whether they present below or above Poupart's ligament or in the region of the lumbar muscles. There is a villous membrane, apparently pyogenic, but the pus is really secreted from the vertebræ or intervertebral cartilages. We cannot, as in the last case, go down and remove the carious bone, but must be content with palliative treatment, and, as the internal organs are generally infiltrated with tubercles, palliative treatment is all that is really indicated. Before the days of antisepsis it was considered fatal to open these abscesses, but now we open them with impunity.

This patient has had other abscesses of this kind opened at different times during the last few years, so that she evidently has considerable vitality.

This abscess presents in the hollow between the lower lumbar vertebræ and the crest of the ilium, and near the median line. This is by no means an indication that the subjacent parts are affected. It may come down from the dorsal region, but more probably from the lumbar vertebræ. Since the parts have no large blood vessels, special care in making the incision is not necessary. Possibly this abscess communicates with the track of an old psoas abscess, which has been opened in front. Incising the abscess and introducing the finger, I find that this is the case, the abscess is only a compartment of a regular psoas abscess which has found its way around the crest of the ilium. I shall have the abscess washed out, a drainage-tube introduced, and the wound dressed antiseptically.

New York Correspondence.

Operations for Multilocular Ovarian Cyst, Pyolsalpinx and Pelvic Abscess, Lacerated Perineum, Spina Bifida and Necrosis of the Tibia.—The Hot Air Treatment of Phthisis.—Some Favorite Bellevue Prescriptions.

New York, May 6, 1889.

Dr. W. E. Bullard, of the Post-Graduate School and Hospital, removed a multilocular ovarian cyst, March 30, which was interesting from its size and contents. The patient was Catherine D., 45 years old, and a seamstress by occupation. Her history was rheumatic. She began to menstruate at 17, and was fairly regular until seven years ago, when her flow began to diminish. A year later it stopped entirely, and has not since returned. About this time, a tumor was felt in her abdomen. It grew gradually until when she entered the Post-Graduate Hospital last month it had attained an enormous size. The diagnosis of an ovarian cyst was easily made, and operation was necessitated by the dangerous symptoms of pressure, etc. Dr. Bullard cut down on the tumor and drew off the contents. There were in all 67 pounds of it, chiefly albuminous. One sac connected with the cyst contained a quart of colloid matter and several small ones contained dark grumous fluid. The solid part of the tumor weighed seven and a half pounds. Both ovaries were diseased and it was necessary to remove all the uterine appendages. The stump was secured to the incision in the abdominal walls, not with pins, but with silver sutures. By this means the abdominal cavity is closed and the stump left open for treatment. Dr. Bullard is a brilliant surgeon, rapid and sure, and the operation was not a long one considering its gravity. The patient rallied well, with little fever. A week later, when the wound was dressed, a mural abscess of considerable size was found, connecting with the sloughing pedicle. Treated with thorough antisepsis, however, it rapidly improved and the patient is now recovering.

March 31, Dr. A. P. Dudley, of the Post-Graduate and Women's Hospitals, operated at the former place for left pyosalpinx and pelvic abscess. The patient was a domestic, 31 years old, a widow with no children, having had one miscarriage two years ago The latter was followed by an illness lasting six months, during which pus flowed from the rectum. There was a history of repeated pelvic abscess, from which the woman was also suffering on her entrance into the Hospital. Dr. Dudley performed laparotomy, removing both tubes and ovaries, which were diseased, curetting the walls of the abscess, breaking up the numerous adhesions, and stitching the rectum to the abscess walls. The result was a rapid and complete recovery. Dr. Dudley has his own way of closing the abdominal incision, using, instead of silver wire, three rows of catgut stitches. First he unites the peritoneum and lets it drop; next the fascia, the seam of which he includes in the next sutures which take in the abdominal muscles and integument.

Dr. A. F. Currier, of the Post-Graduate Hospital and School, performed an operation for lacerated perineum and rectocele, a few weeks ago, under cocaine. The patient was an American, 36 years old. She menstruated at 13, married at 14, her husband dying two years later. At her first menstruation she had a severe cold, which was followed by amenorrhœa for four months. At 15 she aborted with twins, and at 16 gave birth to a child weighing sixteen pounds. The labor was instrumental, long and difficult, and was followed by an illness lasting five months. She was remarried two years ago, and has since aborted twice. Three weeks before operation she was troubled with incontinence. Physical examination revealed extensive laceration of the cervix

anteriorly and posteriorly, cystocele, rectocele and lacerated perineum. Dr. Currier first operated for the lacerated cervix and cystocele, suturing the former with silver wire and the latter with catgut. The patient bore ether badly, and at the second operation for lacerated perineum and rectocele she had severe bronchitis, which contraindicated ether. Accordingly the double operation was done under cocaine, and very successfully, the patient experiencing little pain.

Dr. L. A. Stimson, at a Bellevue clinic, operated on a case of spina bifida. The patient was a year and a half old, the son of Italian parents. He was born with a tumor the size of a walnut over the sacral region. It gradually increased in size until, at the time of the operation, it was as large as a double fist and had a broad base. The diagnosis lay between a cystic tumor and spina bifida, with indications favoring the former. It was aspirated and then a depression could be felt communicating with the spinal canal, which settled the question. At the aspiration ten ounces of clear fluid were withdrawn. The sac immediately refilled and the child grew weaker. It was decided to dissect out the sac and ligate it, hoping to save the child's life. He was given ether and an attempt made at dissection. The sac was so adherent, however, and the child took ether so badly that the operation had to be abandoned for the time. April 22, Dr. Stimson, by operating very rapidly, succeeded in getting rid of the tumor and bringing the child safely out from under the influence of the ether. An incision was made directly down through the sac wall and the sac emptied. The membranes of the cord and the cord itself in part protruded through the opening in the spinal canal, and numerous filaments were attached to the walls of the sac. These, with the terminal end of the cord, were all ligated, the inner part of the sac was cut away, the hæmorrhage was stopped, an elliptical piece of skin was removed, and by these means the sides of the collapsed tumor were nicely brought together and sutured with silk. A drainage tube was inserted at the lower angle and an ordinary antiseptic bandage applied. The child suffered from shock, but stimulation brought him around and left him in fair condition. The wound did nicely, primary union being obtained throughout. Meningitis, however, was developed; there was a temperature of 104°, projectile vomiting, rigidity of the neck, etc. At latest accounts he was doing well under bichloride of mercury internally and cold tubes to the spine externally.

At his clinic, April 15, Dr. Stimson exhibited a case of extensive necrosis of the tibia, upon which Dr. Gwyer operated for him. The patient, a boy thirteen years of age, had slipped on an orange peel nine months before, striking his right leg on the pavement. This accident was followed by fever, swelling, and a discharge. Since then he has been unable to walk upon it. There was enlargement throughout, a sequestrum involving a large part if not all of the tibia being evidently present. There were congestion and chronic inflammation, and the whole leg was literally honeycombed with sinuses. An incision was made over the whole length of the shaft of the tibia, and the periosteum raised, leaving the involucrum bare. This was chiselled away in front and several large and many small sequestra removed. These were easily loosened, being enclosed in pulpy granulation tissue and *débris* with some newly formed bone. The whole of the shaft was necrotic, and below extended to the epiphyseal line, and perhaps involving the epiphysis itself. However, it was thought best not to interfere with it. The involucrum extended entirely around the bone, and with the exception of what was chiselled away in front, it was left undisturbed. The pulpy tissues of the sinuses were scraped out and the cavity packed with bunches of catgut, drainage being obtained from the sinuses near the lower angle. Silk sutures were put in at each end and supporting sutures in the centre. Over this a dressing of curled hair soaked in bichloride of mercury was applied.

The operation was a long one but the boy recovered from the ether well and is doing nicely. This hair dressing is a new thing that promises well. It is aseptic, light, comfortable, and furnishes perfect absorption and drainage; and, where pressure is wanted, as in fractures, it is exceptionally good as it equalizes the pressure.

The treatment of phthisis by the inhalation of hot air apparently is not a success in Bellevue. It is being quite extensively tried, air at a temperature of 450° being used. Although the visiting physician is not ready to make a report of his experience it is understood that the patients have not yet shown much if any improvement.

The operation of grafting a rabbit's cornea on to the eye of a man was successfully performed here last week. The details will appear in the REPORTER very soon.

The following is the prescription for an expectorant mixture much used in Bellevue Hospital:

℞ Ammonii Carbonatis . . . . . gr. xxxij
Extr. Senegæ Fluidi,
Extr. Scillæ Fluidi . . āā f℥j
Tr. Opii Camph. . . . . f℥vj
Aquæ . . . . . f℥iv
Syr. Tolutan. . . . . q. s. ad f℥iv
Dissolve and mix. Dose, a teaspoonful.

As a gargle for inflammatory troubles, Dr. Abraham Jacobi's "Special" is used:

℞ Potassi Chloratis . . . . . gr. lxxx
Tr. Ferri Chloridi . . . . . ♏ clx
Glycerini . . . . . f℥ij
Aquæ . . . . . q. s. ad f℥viij
Dissolve and mix. Used as a gargle and internally in doses of half ounce.

PERISCOPE.

Hysterical Monoplegia in a Man.

At the meeting of the New York Academy of Medicine, March 11, 1889, Dr. Robert Abbe presented a young man, about twenty-five years old, in whom hysterial monoplegia was developed, the mild clonic spasm and its occurrence in a male patient making the case an uncommon one. This patient had fallen and struck on his back on a slippery pavement, had felt a sharp pain, and had at once lost full power to use the right leg. From this time on the right limb had been affected with anæsthesia, the gait had been irregular, and if the patient lay down and moved the limb about, a clonic spasm appearing like an exaggerated tremor was at once produced. Any general effort produced violent trembling due to clonic spasm in the muscles of the neck and abdomen, and partial stoppage of respiration. Exquisite sensitiveness was complained of when a portion of the spinal column opposite the first dorsal vertebra was pressed with a piece of ice. However, the anæsthesia was diminishing, and when ether had been given, though the affected limb had remained weak while the patient was going under its influence, as he was coming out it had been used with the utmost vigor. It had become quite evident that the case was largely hysterical in its nature, when it was also found that by suggestion the patient could be made to complain of the same pain in any other portion of the spinal column touched with the ice. On being forced to run along the wards quite rapidly, he had used the affected limb freely and had not stumbled. Mild clonus, said Dr. Abbe, is a rare affection, and has not been classified among any of the diseases of the nervous system. The monoplegia does not suggest a spinal paralysis. The condition present is probably an hysterical neurosis, perhaps due to shock, and existing without the patient's being conscious that his own ideas are so largely the cause of it.—*New York Med. Journal*, April 20, 1889.

Treatment of Certain Cases of Chronic Uræmia.

At the meeting of the Medical Society of London, April 8, 1889, Dr. Stephen Mackenzie read a paper on the treatment of certain cases of chronic uræmia. He regards uræmia as a poisoning of the nervous system—a toxæmia; and as the poison is developed within the body of the patient, it is an autotoxæmia. References were made to the writings of Grainger Stewart, Dickinson, and Carter, and more especially to the researches of Bouchard, who had described seven toxic elements in the blood in uræmia. The principles of the treatment of uræmia he declared to be three: (1) the elimination of the poisons; (2) the counteraction of the poisons; (3) the prevention of the retention of further poisons. After discussing the first and last principles of treatment, which should always be employed, he proceeded to point out that the value of morphine is to fulfil the second indication. The author next discussed the nature of uræmic dyspnœa, headache, and convulsions, and attributed the beneficial effects of morphine to its freeing the blood-vessels from the spasm induced by the poison in the blood. He referred to the writings of Loomis and his followers, and to cases recently recorded by Mr. Alfred Grace, in which morphine had been administered in as large quantities as from one-half to one whole grain for a dose, by hypodermic injections, with the best results. He concluded by saying he thought enough evidence had been brought forward to show that morphine deserves further trial in uræmia. He does not recommend its indiscriminate use, and in the light of the asserted susceptibility of patients with disease of the kidneys to the toxic effects of opium, it should be given with eyes open to its possible danger. There can, however, be no doubt as to its immediate good in suitable cases, and it is probable more lasting good will result in cases of a curable kind.—*British Med. Journal*, April 13, 1889.

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Physician's Daily Pocket Record, - - 1.00
Reporter and Pocket Record, - - - - 6.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE CHARGE AGAINST THE PHILADELPHIA HOSPITAL.

The last issue of the REPORTER contained an editorial describing the charges brought against certain nurses, or helpers, in the Insane Department of the Philadelphia Hospital, by a newspaper reporter, who had feigned insanity in order to investigate the management of the institution. These charges have been met in a manner highly creditable to the Board of Charities and Correction, which governs the hospital. The President of the Board acting for it, at once addressed an official communication to the District Attorney, reciting the published accusation and asking him to make such an investigation as shall discover in how far they may be true, and to take steps to bring to justice any person who may be shown to have been guilty of cruelty to the inmates. He has also taken steps to have the charges formulated in such a way as to bring them formally before the District Attorney for official notice.

In doing this the Board of Charities and Correction has taken the best step possible to strengthen the confidence reposed in it by the community. It is rather a new thing, in the history of institutions like the Philadelphia Hospital, to invite a thorough judicial investigation of charges made against them. The usual course is to deny the charges and to endeavor to screen those individuals who are directly implicated by them. In deviating from this course the authorities of the hospital have disarmed captious criticism, and shown that they know how to concede what is proper to an excited public sentiment, while awaiting with patience a vindication which shall be without favor or a correction which shall be without prejudice. Whatever the issue may be, as to the details of the charges of cruelty on the part of a few subordinates, the community will be sure to approve the wise and just attitude assumed by those who are indirectly involved in them; and the reputation for humane and skilful management, which the Philadelphia Hospital has of late years come to enjoy, will, we have no doubt, be enhanced by the manner in which the present exigency has been met.

A CASE OF HYSTERO-EPILEPSY IN A MAN.

On account of the comparative rarity of hysteria in men and especially of its severer forms much interest attaches to the history of a case reported by Drs. Andrée and Knoblauch in the *Berliner klin. Wochenschrift*, March 11, 1889. The case was observed at the garrison hospital at Karlsruhe. Instantaneous photographs were made during the several periods of the spasms and from them engravings which illustrate the paper. The following is an outline of the

history of the case. A grenadier, twenty-three years of age, never having had any nervous disease or hereditary tendency of this sort, after great mental agitation, combined with great bodily exertion, was suddenly taken ill with violent spasms, and was brought to the hospital in a state of unconsciousness, on March 4, 1888. On examination in the hospital he was found to be a strongly built, very muscular and well nourished man; all the organs were normal, the pulse was full, bounding and regular, with about ninety-six beats per minute. The respirations were quiet and deep, and somewhat accelerated. There was no contraction of the muscles or wounding of the tongue or lips. A short time after being placed in a bed, the man had an attack of spasms lasting four minutes, succeeded during the same day by similar attacks. From the fifth to the seventh of March the patient had from six to nine attacks of spasms daily, of varying duration and intensity. From this time on, the attacks diminished in frequency, but increased in duration and in intensity, until finally there was developed the typical attack of "*grande hystérie*," or hystero-epilepsy, with the three well marked stages described by Charcot, Richer and others. Always before an attack began, the patient had sensations on the breast, neck and the head, similar to the *aura epileptica*. A most remarkable feature of the case was the fact that the lightest touch upon the right nipple produced the hysterical aura, and this was followed by a typical attack when the nipple was pressed somewhat more firmly or when the skin was rubbed with the finger in a direction from the nipple upward toward the right side of the neck. On the other hand it was possible to suppress the attack in all its periods, and to put the patient in a state of a profound sleep, by rubbing the skin in the opposite direction—from the neck to the right nipple. An attack could not be produced by acting on the testicle, but it was possible to suppress one for a short time by strong pressure on one or both testicles, and also, in like manner, by strong pressure on the abdominal regions on both sides which corresponded with the position of the ovaries in women.

After the fifth day of the patient's stay at the hospital the frequency of the attacks diminished rapidly, and when they had failed to appear for six weeks, he was discharged. After two weeks he had a new attack lasting fifteen minutes. A final attack, lasting five minutes occurred five weeks afterward. During the last five months he had not had any more attacks, but was very well and able to work; and of late he had not had any evidence of having had a nervous disease.

This remarkable case is of great interest, as it illustrates the strange character of grave hysteria, to which the name is etymologically as inappropriate in women as in men. The possibility of developing an attack by pressing the nipple of one side or rubbing the skin of the breast in one direction, and of curtailing the attacks by rubbing the same skin in an opposite direction or pressing upon the testicles is as curious as any of the phenomena observed in hysteria in women. More curious still is the fact that pressure upon the abdomen, over the region corresponding to that of the ovaries in women, should have produced an effect similar to that observed when the ovaries themselves are pressed in hysterical women. This may be partly accounted for upon the theory that the pressure caused a sensation in the spermatic cord which was referred to the testicles, but the fact is none the less interesting.

MILK AND THE PUBLIC HEALTH.

The relation of adulterated, fermented, putrified or infected milk to the public health is a question which has assumed greater importance with the increase of knowledge of the etiology of disease. Adulteration of so necessary a food product as milk needs only to be mentioned to be

condemned. It is now generally admitted that milk which has undergone fermentative and putrifactive changes, is a very frequent cause of diarrhœa in artificially-fed infants. The causative relation between certain products of the putrefaction of milk and other albumenoid substances and choleraic attacks in those ingesting them—known as picnic ice-cream poisoning, stale cream-puff poisoning, etc.—has been demonstrated, and largely through the investigations of Prof. Vaughan. The occasional dependence of epidemics, especially of scarlet fever, and other contagious diseases, upon infected milk is an accepted fact. That milk from tuberculous animals may prove a source of infection has long been a prevalent belief in the profession. This belief finds expression in the axiom that a tuberculous mother should not nurse her offspring. At the French Congress for the Study of Tuberculosis, held in 1888, the opinion was strongly supported that milk from tuberculous cows is a frequent source of infection. A case in point is that of Demme, of Berne, which was mentioned in the REPORTER, August 18, 1888. In this case an infant artificially-fed, and not hereditarily disposed to phthisis, died of tuberculosis of the mesenteric glands, as shown by the autopsy. The cow from which milk for the infant was obtained was killed and tubercle and bacilli were found in abundance in the left lung and pleura. Bacilli were also found in milk expressed from the deepest parts of the mammary gland. The statement that the relation between bad milk and the public health is an important one is seen to rest upon a solid basis. Unquestionably, however, the question of bad milk as a cause of disease and death among infants is relatively so great as to overtop the other evil influences arising from this cause.

The methods of milk supply in general use in Philadelphia and other cities do not protect the consumer against bad milk; in fact, the incentive to the honest producer and dealer is to adulterate the milk, because he is in close competition with dishonest dealers who do. A number of methods have been suggested and tried to protect the consumer and the honest dealer. Systematic inspection has done much to improve the milk supply of New York, among other cities. It is conceded that proper inspection of milk to detect adulteration, together with stringent laws for the punishment of the adulterators, are powerful factors in ensuring pure milk to the consumer. But, however much the accomplishment of this end is to be desired, it really solves but a part of the problem. Milk which has undergone putrefactive changes, or which contains the contagium of scarlatina or the bacillus of tuberculosis is far more to be dreaded than milk which contains an undue percentage of water.

The method of delivering milk in sealed bottles or glass cans is advocated and practised quite extensively. In Philadelphia the method has been employed by Dr. J. Cheston Morris and others. In 1884, Dr. Morris read a paper before the Social Science Association of Philadelphia, in which he advocated the general adoption of this method of milk delivery. It is claimed for the method that since the seal is placed upon the bottle at the dairy, the consumer is protected against the dishonest retailer; and since the producer's name appears upon each bottle, the demand for his brand depends solely upon its quality. Hence the producer has a constant incentive to furnish a good quality of milk. On the other hand, it is urged that the multiplicity of milk vessels increases the probability of the use of unclean vessels; and that the liability of milk to be a means of propagating the infectious diseases is increased by the method, since the vessels are left at houses indiscriminately, whether their inmates are suffering from contagious diseases or not; also that no protection is afforded against tuberculosis.

Prof. Vaughan, so well known for his researches in connection with the putrefac-

tion of milk, has formulated certain rules which, if followed, would ensure a supply of good milk; though the spread of the contagious diseases and tuberculosis by means of milk might not be prevented. These rules comprise the exclusion of diseased cattle from dairies, provision for the sanitary condition of stables, exclusion of improper food, and cleanliness of the cattle. In this way good milk is secured. In order that it may be good when delivered to the consumer, it is to be strained in perfectly sweet and clean cans, and chilled by being placed in running water or ice water until its temperature is at or below 65° F. During this time the milk must be exposed to the air; only refrigerator cars must be used in its transshipment; and its temperature must never be above 65° F. when received by the consumer. To ensure the results sought by this method necessitates a large force of inspectors.

With a supply of whole, unfermented milk ensured the consumer, the problem of preventing putrefactive changes, and of destroying the germs of tuberculosis or the contagium of the exanthemata is probably solved by sterilization with heat. The usual method of boiling milk in open vessels probably destroys any germs it contains—the germs of disease as well as those of fermentation; but the method is open to objections. It is necessary to pour the milk into other vessels, thus it is freely exposed to the air and fermentation is favored. Practically, Caillé has found that "store-milk," after being boiled in an open vessel, when placed in an open dish in an ice-box "turned" after eighteen hours; and that good "bottle-milk" treated in the same way "turned" in twenty-six hours; and that the same milk when left standing in an open room with a temperature of 75° F., had a distinct sour taste and smell after from eight to fifteen hours. Milk boiled under pressure in small bottles for thirty minutes and left in the bottles remained good eighteen days. The very superior results obtained by boiling the milk under pressure would indicate this as the most desirable method.

The method followed and the apparatus used by Caillé were those of Soxhlet. The method is intended more especially for the sterilization of milk for infant feeding in private families. The apparatus is very simple and inexpensive. Practically the method consists in putting milk into five or six ounce bottles, into which a perforated rubber cork is inserted. The bottles are put in a water bath and the water raised to the boiling point. Glass stoppers are then inserted in the perforated rubber corks and the boiling process is continued for twenty minutes. This method and apparatus are largely used in Munich and Southern Germany, and to a certain extent in this country.

It appears that the principle involved in this method is so simple that it could easily be applied to the milk supply of a city. In discussing the method of supplying milk in sealed bottles, it was found that the two objections to the method were the greater probability of milk contamination from unclean vessels, and the danger of spreading contagious diseases from house to house. These objections would be overcome by boiling the bottles after cleaning them; and sterilizing the milk in the bottles before sealing them. Milk so prepared could not cause diarrhœa or cholera infantum, or be the means of spreading tuberculosis or any one of the infectious diseases.

A COUNTY SOCIETY SUSTAINED IN COURT.

It is interesting to note that judgment has lately been entered on a final order of Judge Ingraham of the Supreme Court of New York, sustaining the Medical Society of the County of New York in expelling from membership Dr. James O'Reilly, who advertises a so-called "Woman's Infirmary and Maternity Home," in which the special object seems to be to care for unmarried pregnant women.

In the circulars issued when this institution was first started there were intimations which might easily be construed into a willingness to relieve mothers of illegitimate children of all the responsibilities of their motherhood, as well as to furnish them a place of concealment during the latter part of their pregnancy and their lying-in period. These intimations, and the general methods of Dr. O'Reilly were calculated to arouse suspicion in regard to the motives and intentions of his institution, which posed as a charity, and the New York County Society expelled him, for a violation of the code of ethics—as we understand the case.

As the members of the profession in the city in which Dr. O'Reilly lives and has his "Infirmary" are best fitted to judge of the propriety of conduct which at this distance seems open to suspicion, we have no doubt that he got but his deserts in being expelled from the County Society, and are glad to find that the Society's action is now fully sustained by a judicial decision.

Another Murder by an Insane Man.—A dispatch from Chicago to the daily papers states that a young man, twenty-six years of age, became suddenly insane while in bed, on May 5. After a desperate struggle with his wife, he took their babe from its crib and dashed its brains out against the wall. He then got a butcher knife and tried to kill his wife, but she escaped to the street. The man then cut his own throat with the knife, but did not kill himself. He was secured and taken to the hospital.

It is possible that the man in question had been insane for some time, but had been kept at home by his affectionate but misguided family. The case points to the importance of putting persons with certain forms of mental derangement under proper supervision and, if necessary, restraint at the earliest possible period. This is best as regards the patient's recovery, and is the only way to prevent such horrible acts as are illustrated in the present instance.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

ELECTRICITY IN THE DISEASES OF WOMEN, WITH SPECIAL REFERENCE TO THE APPLICATION OF STRONG CURRENTS. By G. Betton Massey, M.D., Physician to the Nervous Dept. of Howard Hospital, etc. Small 8vo, pp. viii, 210. Philadelphia and London: F. A. Davis, 1888. Price, $1.50.

The appearance of Dr. Massey's book at this time is opportune, and, unlike many books, we believe it will fill a "want," felt by the profession, which has been produced by the publication of the researches and results of Apostoli, Engelmann and others.

The introductory part of the work consists of a concise presentation of the laws of electricity, together with a description of the electrical apparatus necessary for the application of this agent to the treatment of certain diseases peculiar to women. Then follows a systematic consideration of the uses of electricity in gynecology. The author's claims are in general moderate, and fully justified by the present status of the subject. His moderation in statement is less apparent when he strays slightly from the domain of electricity into that of surgery proper. This is perhaps to be expected from one who has studied the subject from the standpoint of the neurologist and electrician rather than from that of the gynecologist.

It is especially pleasing to note that the author regards the presence of pus in the pelvis as a positive contra-indication to the use of electricity.

As already stated we believe the book will fill a "want," and owing to its scientific character and moderate claims it can be recommended to all who reat the diseases of women.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

265. Repression of Menstruation as a Curative Agent in Gynecology. By Eugene C. Gehrung, M.D., St. Louis, Mo. From the *American Journal of Obstetrics*, November, 1888. 12 pages.

266. Food versus Bacilli in Consumption. By Ephraim Cutter, M.D., New York. From the *Virginia Medical Monthly*, December, 1888. 24 pages.

265. Dr. Gehrung, after a short consideration of the functions of menstruation in general, advances and defends the rather startling view that it may be advantageously interrupted by artificial means—vaginal tampons—whenever the flow seems to be greater than a woman can afford to lose. He believes that a flow of from two to four ounces of blood should be regarded as the maximum, and that the loss of quantities in excess of this is injurious to health.

266. It is not pleasant to criticise persons whose motives may be excellent; but how anybody can read patiently the stuff published by Dr. Cutter, we cannot see. The pamphlet before us is like all the rest of his productions which we have seen, and commends itself as little to our approval.

CORRESPONDENCE.

Catarrh of the Middle Ear.

TO THE EDITOR.

Sir: For the past two years we have had numerous cases of acute inflammation of the middle ear, of a catarrhal nature. So frequently have they appeared that they may justly be considered epidemic. Some cases are mild and are relieved after only two or three days of "ear ache," while others are very severe, having a destruction of the tympanum; the chain of bones, and deeper structures, with loss of hearing, leaving an offensive discharge from the ear which continues for months. When there is extensive inflammation in the tympanic cavity there are excruciating pains. In one case of four days standing, symptoms of compression of the brain appeared, after which the patient survived only twenty-four hours. In another case an opening was made above the mastoid process, from which there was a discharge of fœtid pus for several months.

In some of these cases the inflammation seemed to start in the ear, and in others it travelled up the Eustachian tube developing into intense severity after reaching the tympanic cavity Those attacked were of various ages, from one year to middle life. I have not seen one above fifty years of age. The most severe cases were in adult males.

Catarrhs have not been more prevalent during this period of time than in former years, but this particular form seems to be more prevalent.

Diphtheria has prevailed to some extent, but in not one of these cases of diphtheria has there been an extension into the tympanic cavity. I am a firm believer in the germ origin of diphtheria—but am not quite ready to attribute this epidemic to any form of micro-organisms. I believe the cause to be exposure to extreme cold winds; but I cannot explain why we should have such an epidemic, for one does not always follow such severe cold winds when

These cases are seemingly cut short by vigorous and persistent use of anodynes and sedatives — remedies which in diphtheria would be extremely pernicious. Opium alone does not control the pain; I usually combine it with gelsemium, and bromide of potass.

Yours truly,
JOHN M. CURRIER, M.D.

Newport, Vermont,
May 6, 1889.

NOTES AND COMMENTS.

Useful Formulæ in Skin Diseases.

Dr. M. J. Epstein gives the following formulæ as in use in the service of Dr. W. A. Hardaway, at the skin clinic of the St. Louis Post-Graduate School of Medicine (*St. Louis Polyclinic*, May, 1889):

℞ Unguenti vaselini plumbici . . ℥iv
S. Spread on cotton cloth.

One of the most universally applicable and valuable ointments in eczema is the diachylon ointment of Hebra; but owing to the difficulty of preparing it after the original formula, it is now generally made by melting together equal parts of vaseline and lead plaster. It should be neatly and evenly spread on strips of cotton cloth, and fastened to the parts with a roller bandage.

℞ Ung. picis liquidæ . . . . . ℥ss
Ung. aquæ rosæ . . . . . ℥iss
Zinci oxidi . . . . . ℥i
M. S Spread on lint.

This is of especial value in the eczema (chronic?) of children.

℞ Ol. rusci . . . . . f℥i-ii
Ung. aquæ rosæ . . . . . ℥i
M. S. Rub in thoroughly.

Useful in sqamous eczema and also sometimes in psoriasis.

℞ Hydrargyri ammoniati . . . ℥ss
Liq. picis alkalin. . . . . f℥i
Ung. aq. rosæ. . . . . ℥i
M. S. Local use.

Employed in infiltrated eczema and in psoriasis of the scalp. It must not be used over too large a surface.

℞ Acidi salicylici . . . . . ℈i
Sulphuris præcipitati. . . ℥i
Vaselini . . . . . ℥i
Ol. rosæ . . . . . q. s.
M. S. Rub in thoroughly.

The range of application of this preparation is very wide, viz: seborrhœa and scaly eczema of scalp, tinea versicolor, keratosis senilis, and lupus erythematosus.

℞ Emplastri plumbi . . . . . ℥xxv
Pulv. saponis . . . . . ℈iv
Aquæ . . . . . q. s.
Vaselini . . . . . ℥v
Camphoræ . . . . . gr. xx
Acidi salicylici . . . . . ℈v
M. S. Spread on lint.

This is a modification of Pick's compound salicylated soap plaster. It is much prescribed in the clinic for infiltrated eczema, especially of the hands and feet, and is now largely used in place of the more expensive Hamburg plasters of a certain kind. The

amount of salicylic acid may be varied to suit the case.

℞ Chrysarobini . . . . . gr. xl
Acidi salicylici . . . . . gr. xl
Traumaticini . . . . . f℥i
M. S. Apply with a camel's hair pencil.

This combination affords the best results in psoriasis. After thorough removal of the scales, it should be painted directly on the patches, being careful not to put it on the face, or about the genitals. As is well known, chrysarobin occasions considerable dermatitis, and its effects must be watched.

℞ Quininæ sulphatis . . . . . gr. x
Spir. myrciæ . . . . . f℥iii
Glycerinæ . . . . . f℥i
Sodii chloridi . . . . . ℥ii
Aquæ . . . . . q. s. ad f℥viii
M. S. Local use.

There are hundreds of so-called hair tonics, containing more or less of these ingredients, but the one here given is one of the most satisfactory of its kind.

℞ Acidi salicylici . . . . . ℥ss
Zinci oxidi,
Amyli . . . . . āā ℥ii
Vaselini . . . . . ℥ii
M.

The formula above constitutes the well-known Lassar's paste. It may be applied on strips of cloth, or in chronic scaly patches directly rubbed in with the finger. It is of value in many varieties of eczema and intertrigo.

℞ Zinci oxidi . . . . . ℥i
Glycerini,
Mucilag. acaciæ . . . . . āā f℥ii
M. Apply with a brush.

In extensive patches of eczema this paste is very agreeable. If itching is severe, one per cent. of carbolic acid may be added.

The Death of Father Damien.

Father Damien, the heroic Belgian priest who devoted his life to the service of the leper colony in the Sandwich Islands, fell a victim to the disease on April 10. The readers of the REPORTER will recollect that mention was made of his desperate condition in the issue of January 26, and a brief statement of his self-denying labors in the issue of February 16, of this year. Father Damien had resided among the lepers for sixteen years when death came to his relief, and he had seen the population of Molokai renew itself three times, as the average duration of a leper's life is about seven years. Years ago, he became afflicted with leprosy himself, and for a long time before his death was a painful sufferer from the scourge. The latest letters from the leper colony stated that his health was so broken that his death was likely to occur at any time. Father Damien had for assistants two men as heroic as himself. One of these was an Irishman named Walsh. He was a mason by trade, and had been a soldier in the English army. Walsh reached Honolulu in broken health and reduced circumstances just at the time a superintendent was needed to keep the colony in order. He accepted the position, with the result that he is a leper himself to-day and pining for relief in death. Father Damien's other helper was the Rev. M. Conrardy, a Catholic priest formerly connected with the Archdiocese of Oregon, who voluntarily went to Molokai about two years ago to become Father Damien's assistant.

Dr. W. W. Keen and the Woman's Medical College.

At a stated meeting of the Faculty of the Woman's Medical College of Pennsylvania, held May 18, 1889, the following resolution was adopted:

"*Resolved*, that the Faculty of the Woman's Medical College of Pennsylvania have learned with deep regret of the resignation by Prof. W. W. Keen, of the Chair of Surgery in this College. Dr. Keen's enthusiasm as a teacher in a department for which he is eminently qualified, and his unhesitating surrender of time in doing a generous share of Faculty work, have made his connection with the College conspicuously valuable and helpful.

The Faculty also desire to express their sense of personal loss in this severance of relations which have ever been most harmonious and agreeable, and to proffer their congratulations to Dr. Keen in view of his new appointment, with warmest wishes for success and happiness in his future work."

CLARA MARSHALL,
Dean of the Faculty.

—Roger and Gaume have made a report to the Biological Society of Paris upon experiments concerning the toxicity of the urine of pneumonia patients. During the febrile period they state that the urine is two or three times less poisonous than otherwise; with the crisis it reaches its least degree of toxicity, while after the crisis for two or three days it is considerably increased. They think the cause of the toxicity is an unknown poison, perhaps a substance produced by bacteria.

NEWS.

—The Legislature of Tennessee has passed a bill to regulate the practice of medicine in that State.

—The German Ophthalmological Society will meet at Heidelberg from September 13 to 15, 1889.

—An International Congress of Otology and Laryngology will be held in Paris from September 16 to 21, 1889.

—The annual meeting of the American Surgical Association was held in Washington, D. C., May 15, 16 and 17, 1889.

—Dr. William A. Douglass, Emeritus Professor of Anatomy in the Cooper Medical College, died in San Francisco, Cal., March 26.

—The *Nashville Journal of Medicine and Surgery*, April, 1889, announces that the plans for the new city hospital have been submitted, and that bids for the erection of the building will be opened at an early day.

—Dr. Duane B. Simmons, who has done so much for medical education in Japan, died there recently. The *Sei-I-Kwai* Medical Journal, April, 1889, contains a number of appreciative notices of his life and services.

—The Eleventh Annual Congress of the American Laryngological Association will meet at the Arlington House, Washington, D. C., May 30, 31 and June 1. A cordial invitation to attend the meeting is given to members of the medical profession.

—Under date of April 27, 1889, it is reported from Japan that a terrible disease, resembling malignant typhus, has broken out in Anagawa Ken. Of 64 cases, 40 ended fatally within 24 hours. The doctors attribute the disease to the use of bad rice.

—Dr. Charles E. West, of Brooklyn, who began teaching when only 18 years old, is now about to retire at the age of 80 years. For the last fifty years he has been connected with three schools, of one of which, the Brooklyn Heights Seminary, he is now President.

—Willard Perkins, a restaurateur, of Waterbury, Connecticut, died there on April 27, from congestion of the lungs and heart failure, attributed to excessive fat. He was born in Philadelphia, and at the age of 12 years weighed 250 pounds. At one time he weighed 452 pounds. Until he was 20 years of age he was exhibited throughout the country as "Billy Bates, the Philadelphia giant."

—A law to punish drunkenness went into effect in Minnesota on May 16. It provides that "whoever becomes intoxicated by voluntary drinking intoxicating liquors shall be deemed guilty of the crime of drunkenness, and, upon conviction thereof, shall be punished as follows: For the first offense, by a fine of not less than $10, nor more than $40, or by imprisonment for not less than ten, nor more than forty, days; for the second offense, by imprisonment for not less than thirty nor more than sixty days, or by a fine of not less than $20 nor more than $50; for the third and all subsequent offenses, by imprisonment of not less than sixty days nor more than ninety days."

HUMOR.

Our National Navy should be rapidly doubled up with the Cramps working so persistently at it.—*Washington Critic.*

If you feel mad when some rude person runs into you in the street, how must you feel when a locomotor ataxia?—*N. Y. Commercial Advertiser.*

Jings.—"Chops is all broke up. The Sheriff has just seized his meat market." Jangs.—"Is that so? I saw him this morning, and I thought he looked as if he'd lost flesh."—*Lowell Citizen.*

A Successful Affair.—Wife (to her husband, a physician)—"Did you stop at the Vancouver ball to-night, William?" Physician—For a few minutes, my dear." Wife—"Did it seem to be a successful affair?" Physician—"Oh, yes; while I was there a young lady fell in a faint, and I prescribed for her. Here is her father's card."

Walt Whitman, it is related, was called upon the other day by a young man with a large manuscript, which the visitor exhibited, remarking "Mr. Whitman, I should like to read you my drama and get your opinion of its merits." "No; I thank you," responded the good gray poet, "I've been paralyzed once." So was the young man forthwith.—*Ledger.*

Sympathized with Nature.—Granger.—"Doc, thar mus' be suthin' left whar ye pulled thet tooth for me, last week. It's ached ever sence." Dentist (examining the mouth).—"Nothing there, sir, but a vacuum." "How big?" "Why, about the size of a tooth, of course." "Wal' yank 'er out, Doc. I knowed suthin' was wrong. I've heerd that nacher obhors a vackeyum, an' dinged if I blame 'er, 'f she ever got one stuck inter her jaw."

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

LEIDY'S
Elementary Treatise on Human Anatomy.

NEW SECOND EDITION.
REWRITTEN AND ENLARGED.
CONTAINING 495 ILLUSTRATIONS.

By JOSEPH LEIDY, M.D.,
Professor of Anatomy in the University of Pennsylvania, etc.

8 vo. Extra Cloth, $6.00. Sheep, $6.50.

"After a thorough inspection, I am pleased to pronounce LEIDY'S ANATOMY a most excellent work. It covers the entire field in a masterly manner, and deals with subjects entirely overlooked by other authors. It will afford me much pleasure to not only recommend it to the profession, but also introduce it in my school."—S. F. CARPENTER, Northwest Medical College, St. Joseph, Mo.

"I am well pleased with the simple manner in which the complex subject is handled. I very much like, too, the way in which the scientific names of parts, etc., are used, as in most of our anatomical text-books this has proved a source of much trouble and discouragement to those beginning to study. I shall recommend the book to my classes."—W. E. BLOYER, M.D., Professor of Anatomy, Eclectic Med. Inst., Cincinnati, O.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

THE SUBCUTANEOUS USE OF MERCURY IN SYPHILITIC AFFECTIONS.

BY E. BALDWIN GLEASON, M.D.,
PHILADELPHIA.

The treatment of syphilis by the injection of various salts of mercury, both soluble and insoluble, either into the subcutaneous cellular tissue or deep into the muscular tissue, has lately attracted considerable attention. In France the favorite method seems to be the deep injection of calomel suspended in fluid cosmoline; while in Germany a formula consisting of calomel, common salt and distilled water has been extensively used. It is claimed for these methods that abscesses seldom occur, and that the calomel, being slowly changed by the chlorides of the blood into the soluble bichloride, is more slowly absorbed, and thus a more constant and prolonged influence of the drug is obtained than is possible by other methods. It is also asserted that the injections need not be repeated at frequent intervals, as some days must elapse before all the calomel has been converted into a soluble salt and absorbed.

My own experience in the use of subcutaneous injections of mercury has been wholly in the treatment of severe syphilitic disease of the nose and throat, where the prompt action of an antisyphilitic remedy seemed essential to save my patient from disaster. I have always employed corrosive sublimate dissolved in distilled water, using it in the manner taught me by Dr. Carl Seiler. When a solution of corrosive sublimate is injected into the tissues, an insoluble albuminate of mercury is formed, which is somewhat slowly changed into a more soluble compound and absorbed. Undoubtedly subcutaneous injections of bichloride of mercury are more quickly absorbed than those of calomel; yet I am persuaded that if they are repeated not oftener than once in twenty-four hours, a constant and unvarying mercurial action may be obtained as readily as by the injec-

tion of the mild chloride, and with less danger of producing an abscess.

If three grains of corrosive sublimate are dissolved in an ounce of distilled water, a solution is obtained which remains apparently unchanged for months, and is very convenient for use hypodermically. Ten minims of this solution contain one-sixteenth of a grain of corrosive sublimate, which is perhaps the average dose employed by the subcutaneous method in the treatment of syphilis, although it is well to begin with a somewhat smaller quantity and not increase the dose until the susceptibility of the patient to the effects of the drug have been ascertained. The injection may be safely made in the following manner: The syringe having been filled with the quantity of the solution to be used, and the patient's back exposed, he is made to kneel before a chair, and bend somewhat forward. The point of the needle of the syringe is then introduced deeply into the cellular tissue just below the scapula, and moved about in a quarter-circle to be certain that the point is entirely free. The injection is thrown into the tissues somewhat slowly. Placing a finger over the small wound made by the needle, the operator should thoroughly knead and rub the injected fluid into the tissues. Upon the thoroughness with which this is done depends the subsequent freedom on the part of the patient both from pain and also from the danger of an abscess. This is a matter of the greatest importance and should not be overlooked. No immediate pain is caused by the injection. Within half an hour, however, some pain and soreness are experienced by the patient, the degree seeming to vary inversely with the depth of the injection into the cellular tissues and the thoroughness with which the irritating solution is distributed and, as it were, diluted by being rubbed into a large area of cellular tissue. If the injection is simply thrown beneath the skin and allowed to remain there without being distributed, great pain will be experienced by the patient, and, although I have not seen it result, I think an abscess would not be unlikely to occur.

It is hardly necessary to remark that an special syringe should be reserved for this kind of work, to avoid any possible danger of contagion. Corrosive sublimate rusts the needles and, unless especial pains are taken to prevent it, in a short time renders them unfit for use. A good rule is always to wash out both syringe and needle after each injection with clean water, and then draw into the needle a few drops of fluid cosmoline before inserting the wire and putting the instrument away in its case. Even with these precautions the point of the needle soon becomes rough and dull and should be frequently sharpened to avoid inflicting needless pain. The following cases now under treatment will illustrate what may be accomplished by the subcutaneous injection of bichloride of mercury.

Case I.—The patient was a nursing mother, 26 years old, with a puny infant three months old. She had had three miscarriages and had, when she applied for treatment, pains in the bones; her hair had also become much thinner than it had formerly been. The woman was fat and appeared to be in robust, blooming health; but she complained that her throat was sore and that it hurt her to swallow food. Upon examination, the fauces presented the characteristic red lines of syphilitic erythema, running up each of the anterior pillars of the fauces and ending abruptly at the root of the uvula. These red lines are to be seen in every case of syphilitic disease of the nose and throat, although they are not pathognomonic of syphilis, as a similar appearance is presented in other conditions. At the first view, nothing further abnormal was presented; but, upon lifting the uvula and soft palate, upon the pharynx was seen what was probably the lower border of a large ulcerating gumma. Realizing the danger, as stated by Bumstead and Taylor, that a lesion so situated might "even invade the vertebræ and produce necrosis, or even inflammation of the contents of the vertebral canal," the woman was immediately ordered large doses (f℥iii) three times a day of the following mixture:

℞	Hydrarg. bichlor.	gr. i
	Potass. iodidi	℥ ii
	Aquæ	f℥iii

The nose and throat were thoroughly cleansed by means of a spray of Dobell's solution, and the surface of the ulcer carefully dried with absorbent cotton. The soft palate being now drawn forward out of harm's way, acid nitrate of mercury, one part to five of water, was thoroughly applied to the surface of the ulcer, and the patient requested to present herself each day that these applications might be continued.

In spite of this local and constitutional treatment, however, the ulcer continued to increase in size. Within a few days the posterior aspect of the palate and upper part of the posterior pillars became involved.

Knowing that if vigorous measures were not at once adopted to stop the progress of the ulcer, adhesions would form during the healing process which would glue the soft palate irremediably to the pharynx, subcutaneous injections of mercury were resorted to; one-sixteenth of a grain of the bichloride of mercury being at first used daily and afterward every other day; the former treatment in the meanwhile was continued. Within forty-eight hours after the first injection, the ulcer presented a more healthy appearance. In about two weeks it had entirely healed, leaving the fauces entirely normal in appearance, except for the red lines previously noted, which still extended along the anterior pillars and ended abruptly at the base of the uvula.

I was the more anxious as to the prognosis in this case from the fact that I had at the same time under treatment a young woman, who, as the result of a similar affection in a worse degree, had the posterior aspect of the vomer, vault of the pharynx, and remains of the soft palate glued together. Only a small opening from the mouth into the nose, which was just large enough to admit a small knitting needle existed at the junction of the hard and the soft palates. It having been found impossible, even after tracheotomy had been performed and the patient etherized, to dissect through the hard cicatricial tissues with a knife, the small opening already existing in the palate was gradually enlarged by means of the galvano-cautery, until nasal respiration was secured. The voice also was somewhat improved by securing some degree of nasal resonance; but in spite of her improved state the young woman's condition still remains deplorable. In the literature of the subject I find no surgeon claiming very brilliant results in such cases; every operation undertaken has resulted in a partial or complete failure. It would seem then, that the timely use of the subcutaneous injections saved the first patient from great and irremediable damage.

Case II.—The patient was an Irish servant girl, 24 years old. No history of syphilis could be obtained from the patient, but it was subsequently ascertained that she had been treated the year before for a gumma of the septum. She came to me suffering from obstructive nasal catarrh; and a small shelf-like exostosis was accordingly chiseled from the septum. For some days the wound made by the operation apparently did well, but suddenly the nostril operated upon became occluded, while mucous patches in the mouth and upon the pillars of the fauces showed plainly enough what was going on in the nose. Antisyphilitic treatment was at once instituted, subcutaneous injections of one sixteenth of a grain of mercuric chloride being given once a day. In about ten days the nose and throat presented a normal appearance. It is probable that only the prompt effects of the mercury used subcutaneously prevented permanent and complete occlusion of the affected nostril from cicatricial contraction. This case also illustrates the danger of performing any operation about the nose on a syphilitic, until the patient has been mercurialized. Yet after the exhibition of mercury for some days I have seen an obstinate gumma curetted from the nose and a speedy and brilliant result obtained.

Case III.—The patient was an unmarried woman, thirty years old. She had had three miscarriages, and was suffering from a painful swelling upon the left tibia. She presented herself for treatment for a catarrhal affection of the nose and throat, which was, however, of a mild type; but the characteristic red lines upon the fauces, previously referred to, were well marked. She was at once placed upon antisyphilitic treatment, but for some weeks no progress was made. The periosteal pain indeed became almost unendurable, especially at night. Subcutaneous injections of the bichloride had been proposed and rejected by the patient. They were finally, however, resorted to, one sixteenth of a grain of corrosive sublimate being used twice a week. After four of these injections had been used, the periosteal pain ceased at night and the swelling upon the tibia grew less. The injections were now discontinued, the patient continuing to improve upon the treatment which before had had little effect.

Case IV.—This patient was a respectable married woman, who some years ago contracted syphilis from her husband. Large ulcerating gummata existed upon the upper part of each tonsil and extended upon the palate. The patient was extremely emaciated and debilitated. She was ordered cod-liver oil and the mixture given the first patient. One-sixteenth of a grain of mercuric chloride was also injected subcutaneously every other day; and the lesions in the throat, after careful cleansing by the spray of an atomizer, were touched with acid nitrate of mercury, one part to five of water. Under this treatment the patient's health rapidly improved and she gained in weight. At the end of four weeks the

gummata in the throat had left scarcely a trace of their former presence. Unfortunately the woman was obliged to leave for New York City, where she placed herself under the care of another physician. After the lapse of three or four months, she returned in about the same condition as when first seen. Injections again brought about as good a result as in the first instance.

These four cases illustrate fairly well what can be accomplished by the use of corrosive sublimate subcutaneously. It will perhaps be claimed that an equally good result might have been obtained from using mercury either by inunction or by fumigation. If this be so, the filthiness of inunctions or the bother and inconvenience of giving mercurial fumigations render either method much more objectionable than that by hypodermic injection.

Many physicians have doubtless been deterred from using mercury subcutaneously from the fear of giving their patients pain or producing an abscess. The third patient, in the cases cited above, was the only one who complained of the pain caused by an injection. The injection complained of in this instance was the first, which is always the most painful; and in this instance also the injection was not given deeply enough beneath the skin and was not sufficiently well rubbed into the cellular tissue. In other words, the injection was "given in a hurry." The danger of an abscess must be very slight when the method that I have advised is carefully followed. The nearest approach to an abscess that I have observed was a redness and soreness of the skin, which persisted one or two days.

Since writing the above my friend, Dr. Lawrence Wolff, has kindly placed at my disposal an unpublished paper read by him before the James Arthur Meigs Medical Society, at their January meeting. After giving the history of the "hypodermatic use," as he prefers to call it, of mercurials in the treatment of syphilis, both in this country and abroad, and the various preparations of mercury that have been used in this manner, the Doctor states his own experience. Commencing to use mercurials hypodermically in the year 1876, he is among the first, if not the very first, so to employ them in this country. During 1876, Dr. Wolff and his friend Dr. Rosentral gave seventy-seven hypodermic injections, each containing the average daily dose of from one-eighth to one-half grain of corrosive sublimate. In none of the cases thus treated in that year did an abscess occur. Since that time he has given over one thousand hypodermic injections, of never less than one-eighth of a grain and frequently as much as one-third of a grain of the bichloride, without producing an abscess. He employs a half per cent. solution of the bichloride of mercury in distilled water, and injects daily from twenty-five to fifty minims into the cellular tissue of the back and sides of the chest. In none of his cases were more than twenty-five injections given; and, as a rule, a total disappearance of the syphilides resulted after the tenth injection. Even late secondary and commencing tertiary syphilis yielded rapidly under this treatment, when inunctions had failed. No other antisyphilitic remedies were administered during the time that the injections were employed; but an after treatment of five grain doses of iodide of potassium or Blanchards pill was kept up for three months. Only a small percentage of Dr. Wolff's cases showed any relapse and required subsequent injections of the sublimate; while only one case had a second relapse and required the use of the injections for the third time.

1346 Spruce Street.

WESTERN NORTH CAROLINA AS A HEALTH RESORT.

BY JAMES GRAHAM, M.D.,
PHILADELPHIA.

The frightful mortality from the different forms of phthisis in the northern section of our country proves only too conclusively the inefficiency of the medical treatment of the disease. Each winter has witnessed a larger migration to our southern States of sufferers from this and other diseases which our rigorous climate affects injuriously; and as, with our progressive people, supply follows close upon the heels of demand and frequently runs far ahead of it, winter resorts have become so numerous that the physician is now able to show as much judgment in selecting a place as he is in choosing a remedy for his patient.

Western North Carolina has a climate peculiarly adapted to some classes of cases and unfitted for others. Its location makes it easily accessible to our largest centres of population, as good lines of railroad enter it, both from the northeast and also from the northwest, and traverse it, so that almost any part can be reached by a day's journey by stage. The extreme western portion of

North Carolina is about three hundred and fifty miles west of the Atlantic Ocean, and contains a plateau between the Blue Ridge and Allegheny mountains. This is crossed by seven ranges, and extends from southwest to northeast for two hundred miles from the thirty-fifth degree of north latitude. Its northern and southern portions are narrowed by the nearer approach of the mountains which border it. It varies in width from fifteen to sixty-five miles, and includes some six thousand square miles of territory. Most of this territory is occupied by immense forests of almost every variety of tree, with valleys varying in altitude from fifteen hundred to four thousand feet above sea-level. It contains the highest peaks in the United States east of the Rocky mountains, more than fifty of them being more than six thousand feet high. The Blue Ridge is the water-shed of the country, and the plateau is traversed by many rivers.

The temperature of this region varies considerably in different years and is liable at all seasons to sudden changes. The late evenings, the nights and the early mornings are cool in summer and cold in winter, while the middle of the day is hot in the former and warm in the latter season. Frequently a bright sunny day will be followed by a cold damp one.

The sensory nerves of a sick man are a better, though less scientific, indicator of the weather than the thermometer and barometer; and if, as he certainly should, he leads an out-door life, the matter of clothing will be a perplexing one to him. Flannel or silk underwear, heavy or light according to the season of year, is the most suitable, as it will tend to prevent a sudden chilling of the surface of the body; and as at these altitudes one perspires easily on taking active exercise, it will also be found the most comfortable on account of its absorbent qualities. A patient should also be provided with convenient outside wraps, to be worn as required.

The soil in many parts of Western North Carolina contains a red clay, which makes the roads sticky and muddy for days after a heavy rain or snow. These drawbacks are largely overbalanced by the invigorating character of the atmosphere. It affects him like a stimulating draught; it revives his courage, tempts him to exercise, lessens the feeling of fatigue that follows, and, provided he has followed the dictates of his feelings and taken out-door exercise, he is astonished at the keen appetite he enjoys and his freedom from dyspepsia.

We may infer from the foregoing that this mountainous country is no place for persons with cavities in their lungs, or for patients with low vitality from any incurable disease, or for those afflicted with laziness. In the early stages of phthisis, on the other hand, when the patient has still considerable bodily vigor, in convalescence from acute diseases, and for those who are worn down by over-work or worry, this elevated peninsula of the North projecting into the South offers a temperate, bracing climate during the autumn, winter and spring, which is much superior to the enervating climate of the warmer lowlands of the South. When, however, the patient cannot or will not take out-door exercise, then he should go further South, where he can remain at rest in the open air for a large part of the day without suffering from the cold.

While this country has only enjoyed for the last few years a reputation as a Winter resort for Northern invalids, it has been a Summer resort for sixty years for the families of the wealthy planters and merchants of the South. For most of our patients requiring an elevated location in the summer months, the Adirondacks or the Alleghenies in Pennsylvania are preferable to the mountains of North Carolina; but the latter might offer a pleasant change, or even be more suitable for special cases. Here the Summer temperature will frequently run up to 90° in the middle of the day, but the nights are always cool enough to make a blanket comfortable, and there is almost entire exemption from those hot weather plagues—mosquitoes and flies.

Climate is not the only requisite in a health resort, pure water is a good second; and here it can be found in abundance and of the best quality, and where—as is frequently the case—it is brought direct from the spring, the epicure and the critic are both satisfied. When we come to speak of the food, our praise has to be changed to condemnation, as it is bad, even for the South. In the first-class hotels it is probably equal to that supplied in hotels of the same class in the North; but everywhere else the Northern palate will fail to be satisfied, excepting in those houses—which are now numerous—that are kept by Northern men.

Scenery and objects of interest are also important factors in assisting convalescence of patients, and in these respects Western North Carolina is difficult to excel. From many of the mountains there are magnificent and extensive views, but from most of them,

the outlook is disappointing; for there is such an innumerable number of surrounding peaks that when one ascends to the summit he sees nothing but a succession of mountain tops, like billows of the ocean. Frequently, however, one side of the mountain will be so precipitous that the view from its brink will be grand and imposing. But, if the views from the mountains are not all that could be desired, the rivers and streams must ever be the delight of the lovers of the beautiful. The Little Tennessee, the Tuckaseigee, the Nantahalah, the Ocona Lufty, the French Broad, north of Asheville and especially at the Tennessee border line,—these, with their noisy, rapid currents, dashing over rocky beds, through narrow valleys with precipitous sides many hundreds of feet high, afford a never ending delight to the poor invalid. Then the primitive inhabitants one meets, their peculiar dialect, their strange customs and their miserable log-huts, make a progressive Northern man feel as if he had been wafted into a foreign land.

Asheville, the metropolis of Western North Carolina and its railroad centre, is as progressive as a Western town. It has a population of about ten thousand, with electric street-cars, electric lights, underground drainage, banks, telegraph offices, large stores, abundant hotel, boarding and lodging house accommodations and an unfailing supply of pure spring-water, flowing through the town from a huge tank situated high up on the mountain. Its principal hotel, "The Battery Park," is charmingly located above the level of the rest of the town, and is without a rival in the State or a superior in the whole South. But Asheville was not built as a health resort. It is situated on a large open space at an altitude of 2250 feet above sea-level, and is altogether unprotected on the north and west; whereas, on the southeast, where it should be open to the cool breezes of summer, it is hid behind a mountain range; consequently the cold northwest winds sweep it in the winter, and in the summer it is often oppressively warm.

Hot Springs, thirty-seven miles north of Asheville, is beautifully located in the valley of the French Broad, at an altitude of 1326 feet. It has an excellent, large hotel, attached to which are the warm springs; these have a temperature of from 90° to 100°. They are enclosed in two frame buildings; one of these contains a swimming-tank, where ladies, gentlemen and children bathe together; in the other are separate, marble-lined pools, with all the accessories to a most luxurious bath.

Waynesville, on the Western North Carolina Railroad, thirty miles west of Asheville, is a thriving town at an elevation of 2756 feet, and is admirably located for a summer resort. A few miles to the west of it is the majestic Balsam Range of mountains, the tops of which are black from the thick foliage of the trees.

Forty-five miles further west, on the same railroad, is Bryson City, the county seat of Swain. It is a town of 300 or 400 inhabitants, lying in a beautiful valley on the banks of the Tuckaseigee. It has a good hotel, kept by a Michigan family, and numerous boarding houses. There are abundant and easily accessible springs on the adjacent mountains, but it gets its water supply from wells. Its elevation is 1747 feet above sea-level, and with a pure water supply it would be a desirable winter resort. Ten miles away, on the Ocona Lufty river, is an Indian settlement and training school.

Franklin, on the Little Tennessee, is twenty miles south of the railroad, has 300 or 400 inhabitants, is in a rich agricultural country, and is at an altitude of 2141 feet. The scenery is uninteresting and the water supply objectionable.

The Highlands, a new resort settled by Northern people, is on the main stem of the Blue Ridge, at an elevation of 3817 feet. It has an admirably-kept hotel. Satulah and Whiteside mountains are easily accessible and, being isolated peaks, afford extensive views. Highlands and Oweacaluco Falls are within short distances. The Highlands are a delightfully cool and popular resort in the summer, but the water is obtained from wells; as it is situated on the top of the Blue Ridge, showers of rain are of frequent occurrence.

Twenty miles south of Asheville by rail is Hendersonville, a prosperous town of 1200 inhabitants, built at an elevation of 2167 feet. Three miles away and charmingly located is Flat Rock, the oldest of these summer resorts.

Thirteen miles east of Asheville the railroad crosses the Blue Ridge, and half-way down its eastern slope passes "The Round Knob Hotel," 2000 feet above sea-level. It is in the neighborhood of the highest peaks, is a summer hotel, and has an abundant supply of the best water, and also a more than abundant rainfall.

These are only a few of the resorts of Western North Carolina; "the woods are full of them," and each one claims to be the best—not of the State, but of the United States.

A pleasant and beneficial way of changing one's banishment into a vacation is to take a tramping or riding tour. Saddle horses can be hired at five dollars a week. A plentiful supply of pockets will carry all the essential luggage, and, if desired, a trunk can be forwarded by express from town to town. It would be advisable to spend the first week at, say, Asheville, taking a walk each morning and afternoon. After this preliminary training, with a map and compass in the pocket—but no firearms, as only honest, innocent and hospitable people will be met—you start forth, being careful not to attempt too long walks at first. Any house you stop at will provide you with dinner, and also put you up for the night. A request (not a hint) for chickens, eggs, butter and milk may supply you with a palatable meal; but if not, your appetite will show its quality and edge by feasting on fried pork, saur kraut, hot corn-bread with molasses, and black coffee; the stomach will digest it as easily as it would a meal at home that had been ordered by the doctor and prepared by the nurse. As there will probably be only one room in the house, the guest will occupy it as a bedroom in common with the host and his family. On account of the difficulty of getting an abundance of nourishing food, and as such a supply is so important for an invalid, it would be advisable, when possible, for the patient who is taking this tramp to stop overnight at a town where reasonably good fare can be obtained.

The most important fact in regard to this country is that, owing to the cheapness of living, the thousands of the working classes who are excluded by the expense from a prolonged stay at most health resorts, can here live more cheaply than they could at home. Boarding at farm-houses, off the line of the railroad, can be obtained at from five to seven dollars a month. To a Northern man it would be wretchedly poor living, but if he were willing to pay ten dollars a month, the fare would probably be found satisfying. For many consumptives nothing but a permanent change of climate is of any avail, and frequently such a change is required by the entire family. If their financial resources are limited, Western North Carolina offers them peculiar advantages. Building material is plentiful and cheap, eligible locations are innumerable, land can be bought for a trifle, and with, in the winter months, chickens selling at eight cents a piece, eggs at eight cents a dozen, and in season an abundance of delicious fruit worth so little that it is almost given away, a family could be provided with every comfort, be surrounded by the grandest scenery, breathe the most invigorating air, and be exposed to no extremes of temperature at any season of the year. These advantages are so numerous that the probable result will be, in the course of years, that this section of country will be inhabited mainly by Northern invalids and by those who follow in their train.

COLOR-SENSE, AND COLOR-BLINDNESS AMONG THE CHINESE, BASED ON AN EXAMINATION OF TWELVE HUNDRED PERSONS.

BY ADELE M. FIELDE, M.D.,
SWATOW, CHINA.

A love of vivid colors is manifested in all branches of Chinese decorative art. The walls of public buildings are commonly adorned with paintings—historical, dramatic or conventional. Porcelain dishes, paper scrolls, and gauze fans are made to glow with tints that are at once delicate and brilliant. The shoes of all bound-footed women and the costumes of all actors are covered with variegated embroidery. Countless hues are shown in the silken fabrics which are made into gala-dresses for both men and women. Children, on festive occasions, are always gorgeously attired. Not only little Joseph, but also all his brethren appear in coats of divers colors; and no one thinks it amiss to put on a cap of scarlet, a tunic of buff, trousers of green and shoes of pink. Whether in garb or in pictures, there is nothing in Chinese taste that forbids the juxtaposition of purple and green, of rose and orange, or of any other known tints. Like nature herself, they boldly array themselves in all colors, and the experienced eye is no more offended by their tegument than by that of a mandarin duck or a macaw.

A few colors—black, white, red, yellow, light blue, dark blue, bright green, dull green, and flesh color—have each a name of one independent syllable, while their shades are indicated by prefixed adjectives. Many other colors are designated by reference to familiar objects, as "peach-blossom" for pink; "pig's liver" for brown; "coir-palm" for russet; "ashes" for drab; and "grapes" for purple. Dye-stuffs furnish terms for several colors, and "ink-water,"

thus used, becomes a comprehensive appellation for pale gray; but it is not easy to see why the effects of logwood dyeing should be termed "celestial green" when manifested in satin, though "red night" has a poetic sound for the same shade in cotton goods.

The fact that the cloudless sky is always called green by the Chinese, and their lack of precision generally in regard to colors, led me long ago to consider them deficient in color-sense. As I could find no account of their ever having been scientifically tested for this defect, I read last year the books of Prof. Holmgren and Dr. Jeffries, procured Dr. Thomson's stick of Berlin wool-tests, and thought myself equipped for preliminary investigations. I have now tested twelve hundred persons, and have found among them twenty who are either red- or green-blind. The two sexes were equally represented in the number tested. Among the six hundred Chinese women, I found only one who was color-blind by Thomson's tests. This woman was completely green-blind; and all her four sons were color-blind—the eldest three completely green-blind and the youngest completely red-blind.

Among the six hundred men tested, nineteen were found to be color-blind. This number includes the four sons of the color-blind woman just mentioned. Of these nineteen men, thirteen were completely green-blind, five were completely red-blind, and one was incompletely red-blind. The last was a brother of one who was completely red-blind. The nineteen color-blind men included eleven farmers, two teachers, two students, one hospital-assistant, one clergyman, one mason, and one boatman.

By taking the forty skeins of yarn, which are suspended upon Thomson's stick, and piling them in confusion upon a white cloth, I was able to observe, as recommended by Holmgren, the action of the hands in the selection of colors; while the brass tags upon the skeins helped me in making quick record, for future reference and comparison, of the selections made by each individual. I did not, in testing, use the names of the colors; but I first held up the green sample skein, and said: "I am going to pick out, from the pile of yarns, all that are of the same color as this one, whether light shades or dark. Then I shall mix all the yarns together again, and ask you to pick out the same ones that I picked out." When I had taken out all the green yarns, I asked all to look sharply at them, so that they might easily recognize them again. By first showing what I wished them to pick out of the pile, I saved much time in testing the normal-eyed, while I gave no undue assistance to the color-blind.

Upon those found to be color-blind, the tests were repeated, often many times. One color-blind man was very desirous of learning how to distinguish the colors, and as he was at leisure, he remained by my side and gave close attention while a hundred other persons were tested; and yet, after having been repeatedly allowed to "try again," he made precisely the same mistakes as in his first examination. To green he not only added the usual "colors of confusion," but also pale pinks; while with pink he invariably matched bright blues, without adding any of the greens. This young man, like many others, made marked effort to discover differences in the fibres of the wools, or to find some means of distinguishing the skeins otherwise than by their color. Nine other of the twenty color-blinds in the first test also matched green with pink; but of these nine, eight were proven by the second test to be green-blind, matching pink with green.

In all cases where there was doubt of the patient's clearness of vision, tests for form were applied before the tests for color.

I have, following Young and Helmholtz, set down as red-blind all those who, in the second test, matched pink with blues only; and have set down as green-blind those who in the same test matched pink with greens alone, or with both greens and blues. Nine among the thirteen set down as green-blind matched pink with both blue and green.

The persistence with which more than half of the twelve hundred persons tested matched green with blue is remarkable. Even the brightest blues were added to the selected greens after repeated injunctions against so doing. While the tests established the fact that a much smaller percentage of Chinese women than of Chinese men are color-blind, yet those men who by their out of door lives had gained a greater degree of mental training than is possessed by their secluded women-folk chose the correct colors as rapidly as did the women, and no oftener added blues to greens. While there was an almost universal lack of discrimination between green and blue, two colors distinctly named in their own language, the tests afforded by Thomson's skeins, prepared expressly for testing railroad employés for red and green blindness only, were insufficient to prove, what I

now suspect, that many Chinese are violet-blind.

The number examined, twelve hundred, is too small to rely upon for a percentage of red- and green-blindness among the Chinese. Further tests would add nothing to its value, unless subjection to the examination were made compulsory, for many of the color-blind would avoid being tested through fear of appearing stupid before their neighbors. Moreover, the dislike of the Chinese to everything which is not evidently profitable, and their dread of evils that may come to them through occult influences, make it difficult to test any large number. Those examined by me were mostly members of the mission schools and patients in the mission hospital, together with the dwellers in some hamlets, where I endeavored to omit no one from the test.

The proofs of color-blindness must always appear startling to normal vision. It gives one qualms to realize how little one knows of the consciousness of one's neighbor, and how difficult it is to think how the world must look to one who sees the same hue in a tea-rose and a pea-pod, in a rosy cheek and an azure eye, or in a bay horse and a peacock's tail. Even the stolid Chinese appear to be deeply impressed by the exposition of color-blindness.

REPORT OF A DEATH UNDER ETHER.

BY. A. W. RANSLEY, M.D.,
VISITING SURGEON TO THE PHILADELPHIA HOSPITAL.

Death under ether is a comparatively rare accident; but it occurs often enough to make it desirable that every case should be placed on record to assist medical men in forming their judgment of the relative value and safety of different agents used for anæsthesia. For this reason, I give here a brief account of a death which recently took place during an operation undertaken by me in the clinic of the Philadelphia Hospital.

The patient, D. A., 36 years old, was admitted into the Surgical wards of the Philadelphia Hospital about three months ago. The diagnosis was: Coxalgia. On taking charge of the wards on the 1st day of April, 1889, I found the patient suffering extreme pain. He was anæsthetized and examined, and extension was applied. The suffering was considerably ameliorated, the relief continuing for about one week, when his suffering returned and it was found expedient to take off the extension. It was now found on examination that pus had commenced to be formed, and an operation was advised for its speedy evacuation. Accordingly, I had the man brought before the class on May 18, and etherized. The condition of the patient did not contraindicate the use of ether or the performance of the operation. In fact it was imperatively necessary that free vent should be given to the pus.

The patient acted well under the ether (the pulse being moderately strong and regular) until the joint had been opened, when an enormous quantity of pus was evacuated. It was not until the abscess had been opened that any evidences of the terrible calamity that was to follow, showed themselves. Now, however, the patient's countenance suddenly changed; his face became cyanosed; his respirations became shallow and gasping; his heart fluttered, and death speedily ensued. Although everything that could be done for the patient was resorted to, the man died almost as if struck by lightning. It took fully twenty-five minutes to get the patient under the influence of the ether, but the operation was performed in a very short space of time,—fifteen minutes, so that the death occurred about forty minutes after the etherization was begun. Ten fluid ounces of Squibb's ether had been administered, by means of a cone formed with a towel, an opening being left at its apex, by one of the Residents of the Hospital.

In accordance with the law, an autopsy was held by the Coroner's physician; and no direct cause of death was discovered. To my mind it appears that the cause was the effect of the comparatively sudden evacuation of an enormous quantity of pus from a subject already weakened by disease and under the influence of an anæsthetic which—however rarely—certainly *sometimes* acts as a dangerous depressant.

The previous etherisation was without alarming symptoms, and the last gave rise to no anxiety until immediately before the fatal termination.

Whatever may be the correct theory as to the manner in which death was produced in this case, I think it proper to state the facts of it for the information of my professional brethren.

—Professor Billroth, of Vienna, celebrated his sixtieth birthday April 26.

SOCIETY REPORTS.

SIXTH CONGRESS OF THE ITALIAN SOCIETY OF SURGERY.

AT BOLOGNA, APRIL 16, 17 AND 18, 1889.

(Specially reported for the MEDICAL AND SURGICAL REPORTER)

(*Concluded from p.* 632.)

PROF. CASELLI, of Genoa, read a paper on the

Extirpation of Goitre,

in which he said: Up to date, I have done seventy-eight extirpations of goitre, with but one case in which complications occurred. Out of this number, I think I have extirpated the thyroid gland entirely in fourteen cases; I say I think I have done so, for during the operation, amidst the blood and numerous ligatures, one cannot positively state that some of the degenerated gland might not have been left in the wound. The latter accident is sometimes a happy occurrence for the patient, for the function of the part left preserves the patient from the grave general accidents which are often consecutive to a complete extirpation.

In one case, I operated upon a woman who presented an enormous tri-lobed goitre; I first extirpated the right and median lobes of the tumor. One year later, I extirpated the remnant of the goitre, the left lobe; seven days later the patient presented already very severe symptoms of the goitre cachexia; the urine was albuminous, and the number of blood globules had fallen to 2,900,000 in a cubic millimeter. These symptoms, however, became less marked; seventeen days later the number of blood globules had risen to 3,600,000, and this favorable change was explained when simultaneously a small tumor appeared in the crico-thyroid space, formed by a fragment of the gland which had escaped extirpation, and the consecutive development of this saved the patient from a fatal cachexia.

As regards the consecutive general phenomena, I think that a total extirpation of the thyroid body is much more serious if it is practised on young persons. It seems that the importance of the thyroid body in reference to the functions of the organism diminishes with increase of years. The nature of the tumor must also be taken into consideration. The tumors which have brought about a complete abolition of the physiological function of the thyroid body, can be extirpated without any fear of subsequent bad results; but if one has to deal with young persons, to whom the thyroid body is necessary, it would be useful to leave in place a certain portion of the gland.

Bruns and Kocher attribute the alterations of the tracheal and laryngeal cartilages, which are met with in goitre, to a fault of nutrition, due to a compression of the inferior thyroid artery. I myself think that these alterations are due to the direct compression of the tumor, for these alterations disappear when the goitre is extirpated.

DR. BASSINI, of Padua, said: In 1884, I extirpated a large goitre in the case of a young woman, who, after the operation was seized with symptoms of the cachexia strumipriva; but these symptoms soon disappeared. At the same time, there appeared on the sides of the neck, in the supra-clavicular fossæ, little tumors, which brought about the complete cure of the patient. Three of these nodules I extirpated for microscopical examination; they were thyroid adenomas, which convinces me that the tumor which developed in the neck of our patient was of thyroid origin.

DR. TRICOMI, of Rome, read a paper on the

Absorbent Power of the Bladder.

I have studied the power of absorption of the bladder with the healthy and pathological epithelium, in rabbits, dogs and guinea-pigs. I have used mechanical irritation, such as the introduction of a foreign body into the bladder, to produce the epithelial alterations. The following are my results, taking as a comparison the absorption of the same substances by the hypodermic method of administration.

In a bladder, having a healthy epithelium, the absorption is equal to that which takes place from hypodermic injection, with the following substances: sulphate of strychnine, medicinal prussic acid, chloroform, sulphuretted hydrogen. The absorption is less rapid for cantharidine, carbolic acid, corrosive sublimate, morphine, and especially for cocaine; for, to obtain in rabbits the same toxic effect as with one-half grain injected hypodermically, we must inject into the bladder from two to two and a half grains of cocaine. Again, if we inject putrefied

liquids into a healthy bladder, we get no results.

In cases in which the vesical epithelium is in a pathological state, absorption of substances of the first series—strychnia, hydrocyanic acid, and chloroform—is the same as by the hypodermic method. The absorption of substances of the second series is less rapid than in cases in which the bladder is normal. Injections of micro-örganisms has always been followed by positive signs of intoxication in a bladder the epithelium of which has been mechanically and chemically altered. In a bladder undergoing a suppurative process, the absorption of gaseous substances is as rapid as after hypodermic injection; the absorption of bacilli is also very rapid.

Dr. d'Antona read a paper on

Splenectomy following a new Febrile Infection due to a Special Bacillus.

The following case occurred in a patient who presented himself at my clinic, and it constitutes what I think to be a new disease. A child, two years and a half old, son of a physician, was attacked with a left pleurisy with effusion; he recovered, the exudation being absorbed. Two weeks after the disappearance of the effusion, a gastro-intestinal catarrh accompanied by jaundice set in. The child recovered; but from this moment began a sub-febrile state, with a temperature that has gradually increased from 100.2°, 102.1° up to 104° Fahr. in the evening, the thermometer marking 100.2° in the morning. An examination of the abdomen gave evidence of a tumor of the spleen. The child was then taken to the country and for several days he became worse; the thermometer in the evening went as far up as 105.4°; but on the thirteenth day the fever disappeared.

During these stages of aggravation, the spleen was excessively hypertrophied; later the splenic tumor persisted, notwithstanding the general amelioration in the state of the patient, who was treated with quinine, arsenic, and the mercurial preparations. When he was brought back to town in a splendid house and in a most healthy locality, far from any malarial influence, he was again seized with fever, and one month after his return, he still had a temperature of 101° in the axilla. His general state, however, remained good; he had a very good appetite, ate a great deal, was on his feet, and walked even with a temperature of 104° Fahr. The fever was of the continuous type; it never was intermittent and was never accompanied by chills or sweats. The spleen, however, always increased in volume. An antimalarial treatment was then recommended, but it proved useless. The pulse was small and gaseous. The intellectual faculties were well preserved. All belief in a malarial influence had to be put aside; we had to deal with a special infection of the spleen, as this organ increased in size with the fever.

I proposed the extirpation of the spleen, which was so much hypertrophied and indurated that it reached down to the right iliac fossa. The operation was permitted, and on the same day on which splenectomy was performed there was a reduction of temperature to 99°; then a slight fever, reaching in the evening to 100.2° and even 102° developed. The child ate well. Then supervened a gastro-intestinal catarrh, the temperature went up to 104°; then came a purulent otitis, with a temperature of 105.5°; the liver increased in volume, until it extended beyond the umbilical line, but decreased in size afterward and returned to its normal size. The child was at this time in good health for about five months, when he died of tubercular meningitis, which might have been transmitted to him by his father, who was then treating two patients suffering with the same disease.

The extirpated spleen weighed as much as one-tenth the total weight of the body. An examination of the blood before the operation gave a negative result. The blood obtained from the spleen, gave rise, eight days after the operation, to colonies of bacilli exactly similar to typhoid bacilli. Bacilli developed very rapidly on gelatin and water at the temperature of 64.4°; but on potatoes this bacillus proved absolutely sterile, which is an important point in the differential diagnosis from the typhoid bacillus. Inoculation of animals with this bacillus gave negative results. From these studies I infer that we had to deal with an infectious disease, not yet described.

Dr. Ceci draws attention to the unexplainable relation which seems to exist between tumors of the thyroid body, spleen and tonsils, and menstruation. The following observations he made on a young woman from whom he removed the spleen, three years ago. Twenty days after the operation an hypertrophy of the thyroid gland developed; four months later, the tonsils became very much enlarged and one had to be removed. Ten days after this last operation the goitre had disappeared.

Dr. Salvati, of Naples, read a note on

Cerebral Grafting,

and said: I have made the following experiment on two dogs; I have exposed a part of the cerebral cortex, with an oculist's lancet, and removed a small portion, about the size of a pea, from a convolution, and placed it in sterilized water at 77° Fahr. To obtain complete checking of bleeding, I used electricity; one of the electrodes was placed on the back of the dog, the other, which terminated in a platinum wire, in the convolution which had been cut; the hemorrhage was checked completely in ten seconds. The divided part was then reapplied as a grafting; the adhesion and result were perfect, as shown by the specimen before you. It is therefore possible to rely upon the uniting of two fragments of cerebral tissue.

Dr. Ruggi, of Bologna, reported a case of

Resection of the Liver.

A woman came to me with a bi-lobed tumor in the right hypochondriac region, which by percussion appeared to be covered with intestine. An hydatid cyst of the kidney was suspected; but this hypothesis was soon given up, for we found no blood and no albumin in the urine. I performed laparotomy, and found two enormous echinococcus cysts in the liver, one anterior and superficial, the other posterior and deep. I enucleated them and then tried to unite the sides of the large opening which I had made in the liver; but I could not succeed. I then resected three inches of liver tissue so as to make the cut regular, and fixed the surface of the liver to the border of the abdominal parietes. In the first few days, I was obliged to change the dressing very often, on account of the persistent flow of bile which escaped from the cut section of the liver; but gradually this secretion diminished, and the patient recovered.

A microscopical examination of the resected portion of the liver showed me that the orifices of the biliary channels remained open on account of a new formation of connective tissue. I do not think that we must follow Loreta's process, which consists in letting the liver remain free in the abdominal cavity, after having excised a portion from it; although this practice succeeds in lower animals. I shall always recommend, in operations on man, to suture the margins of the hepatic wound to the sides of the wound in the abdominal parietes.

Dr. Ceccherelli says that he uses Paquelin's thermo-cautery as a hemostatic. He wishes to know how Dr. Ruggi stops the hemorrhage, which is ordinarily very severe and which has often been the cause of death of the animals on which he has experimented. He also thinks that the animal dies if a quantity of the organ greater than one-third of the total volume of this organ is extirpated.

Dr. Ceci: Can not the biliary channels, which remain gaping on the cut surface, be tied, and how is the bile carried out when the section has been made with the knife or the thermo-cautery?

Dr. Bottini: How is it that Dr. Ruggi, in his experiments, cuts portions of the liver and then allows the organ to return into the abdomen, without concerning himself about the hemorrhage; and yet the animals live, while those of Dr. Ceccherelli all die of hemorrhage?

Dr. Durante explains this difference by the fact that Ruggi's animals were rabbits and guinea-pigs, and those of Ceccherelli were dogs, in which the liver bleeds very readily. With a good control of the bleeding, one-half of the liver of an animal can be removed without killing it. As to ligaturing the opened biliary ducts on the surface of the cut, this is impossible. To prevent the external flowing out of the bile, we must, before we operate on the liver, excite a localized adhesive peritonitis between the parietal and visceral layers, and then cut the liver with the thermo-cautery.

Dr. Loreta does not think that the effusion of bile into the peritoneum can have any bad consequences. He thinks that the bile of the biliary vesicles has toxic properties which the bile of the liver does not possess.

Dr. Postempski has made experiments on dogs to study the resistance of the peritoneum to the action of the bile; he has found that the peritoneum of dogs supports very well a certain quantity of bile, if it is effused at once; but it does not resist a continual flowing out. He has found biliary pigments in the urine. He thinks that the cause of death is peritonitis, but a non-septic peritonitis. He has seen that in dogs limited resections of the border of the liver occasion a very slight hemorrhage, while incisions on the concave or convex surfaces of this organ are followed by death.

Dr. Cecchini says that, in his numerous experiments, he never had any hemorrhage either in rabbits or in dogs.

Dr. Tansini asks what are the symptoms presented in case of bile effusion into the peritoneum?

Prof. Clementi read a paper on

Battey's Operation,

and said: This method deserves to be seriously considered as it is a certain method of curing rebellious metrorrhagias. In the case of a woman 40 years old operated on by me three years ago, the patient had suffered with very severe metrorrhagia for eight years previous. The trouble was probably multiple fibro-myoma of the uterus. As every means employed had failed, I did a salpingo-oöphorectomy, in preference to a supra-vaginal hysterectomy, the first operation being much less serious than the second one. The cure was complete in nineteen days, and has persisted up to date, which makes three years.

The bottom of the uterus, which before the operation, was three inches above the symphysis pubis, is now on a level with it. The general state is very much better. The only things of which the patient complains are headache and congestion of the face which occur at periods corresponding to menstruation. Is Battey's operation to be performed in all cases of metrorrhagia or tumors of the uterus? Yes, for all the cases in which other treatment has failed.

Dr. Bottini: After the publication of Meyer's statistics the operation of Battey has lost ground, and it seems to-day that the intervention is justified only in cases of grave hysteria. It is true, that after the extirpation of the ovaries the uterine tumors diminish in volume and cease to grow, but when the abdomen is open why should we restrict ourselves to the extirpation of the ovaries and leave the uterus in position?

Dr. Bassini: Although I am very much in favor of the extirpation of the uterus, I nevertheless meet with cases in which I am obliged to employ Battey's operation; that is, in cases in which the tumor is interstitial and deeply situated in the posterior wall of the uterus. The results obtained have been good—cessation of metrorrhagia and sometimes a considerable diminution in the size of the tumor.

Dr. Durante: By the electric treatment, much better results are obtained than by oöphorectomies. With this method I have had but one failure. I think that before having recourse to the operation, the surgeon must first try the electric treatment; a few seatings will be sufficient to tell whether or not electrolysis will do any good.

Dr. Bendanti read a paper on

Trephining in Epilepsy.

I have applied the trephine in the case of a man, 37 years old, for extremely severe convulsive phenomena; he was suffering at the same time from an intercurrent hemiparesis. No neoplasms could be discovered, although the cerebral cortex was incised. Still recovery from the operation was obtained, and the epileptic phenomena have not reappeared; this I attribute to the strong effect of the operation on the œdema of the centers of this region; and I think the treatment of epilepsy by trephining is justifiable.

Dr. Clementi does not think that the brain should be too often exposed, as the results of intervention, except in cases of abscess, are often negative.

Dr. Bassini: As it is always difficult to arrive at a certain diagnosis in lesions of the cortex, I think it is allowable to interfere, if only for exploratory reasons; especially if we meet with incurable epilepsy. I remember one case in which there was very severe excitement, and a depression of the left parietal region; the condition was very much ameliorated by an operation; hence, I think that our colleague is too absolute in his proscription.

Dr. Bendandi: I do not think that trephining has been abused in the treatment of epilepsy, and if in tumors of the cerebrum surgery has not always been the high trump, yet we must recognize that it is our only chance of cure.

Dr. Maraceo, of Naples, reported two cases of

Oöphoro-salpingectomy for Severe Nervous Troubles.

A young woman suffered from the age of 15 with convulsive attacks, especially severe during her menstruation; she tried to commit suicide on three different occasions. She had complete retroflexion of the uterus, with lesions of the appendages. As she attempted a fourth time to commit suicide, I had recourse to the following operation: I removed the two ovaries, which had undergone cystic degeneration, and the two tubes, which were chronically inflamed; I destroyed the numerous adhesions which existed between the intestinal coils and the anterior surface of the uterus, and having straightened this organ, I fixed it to the abdominal wall. The painful attacks disappeared, and the patient is perfectly well.

I also performed oöphoro-salpingectomy on a woman, suffering with very severe nervous trouble. For several years after, she suffered with periodical hematemesis,

but without any bad effect on her general health.

Drs. Cizzoni and Poggi, of Bologna, read a note on

Reconstruction of a Bladder,

and presented a dog from which they had removed the bladder completely. This organ was then reconstructed with a portion of the intestine, to which the operators sutured the urethra and both the ureters. The animal is perfectly well and his urinary functions are perfect.

Dr. Babacci, of Macerat, read a note on

Elastic Suture of the Liver.

To obtain a complete checking of bleeding, after an incision has been made into the liver, it is necessary to suture this organ, in such a way as to establish perfect adhesion to the affected surfaces. For this purpose elastic sutures are best. Not one single animal on which I have tried this method of suture has suffered from peritonitis or other infectious disease. These sutures with the elastic thread, allow a certain increase in size of the organ, without tearing the tissues. The extremities of the elastic thread are connected with the sutures by a silk ligature.

Reports of Clinics.

PHILADELPHIA HOSPITAL.

CLINIC ON DISEASES OF CHILDREN—DR. STRYKER.

Jaundice and Ophthalmia Neonatorum.

I am able to illustrate this morning, in the same patient, two affections of very early childhood which you will be called upon to treat. This child is hardly six days old. It has an intense yellow staining affecting the whole face and body. As a general rule, the affection is much less marked than in this case. The coloration comes on upon the fourth or fifth day after birth, and remains from five or six days to two weeks, and then gradually shades off in color as the biliary pigment is taken up. It is a species of jaundice, and is called icterus neonatorum. The exact cause is unknown, but it is supposed to be due to the alteration of the circulation through the liver at birth. In most cases it calls for no treatment, but in other cases a gentle purge, such as sweet oil or castor-oil, is indicated.

Another interesting feature of this patient is an irritation about the eyes, which has been quite severe. It was first noticed on the second evening after its birth. Although the eyes have been carefully treated and great improvement has occurred, you can see the redness of the conjunctivæ and the yellowish matter that seems to be smeared over them. This is purulent ophthalmia, ophthalmia neonatorum, and it demands prompt attention. An ordinary catarrhal conjunctivitis, in which only a little dry mucus is found in the corner of the eye in the morning, will usually require little attention except bathing with warm water. Breast-milk is used for it by the mothers. In ophthalmia, however, the conjunctiva becomes red and swollen, and inside of twenty-four hours, it begins to pour out a secretion, at first thin as in all such inflammations, but soon becoming viscid and gluing together the edges of the lids and filling up the chamber between the eye-ball and the glued lids. It soon, also, presses so much on the eye-ball as to jeopardize it, to say nothing of the danger of the extension of the inflammation to the corneal conjunctiva.

What is supposed to be the cause of this disease? In an ordinary mild case, possibly the effect of cold or of dust getting into the eye, or an irritation of the eye from washing may be sufficient explanation. But in an attack such as this, the source of the infection is either in an irritating leucorrhœa or in a gonorrhœa. In the great majority of cases, the eye is destroyed or there is such a deposition of inflammatory products as to leave trouble for life.

Rapidity is of all importance in the treatment of such cases. First cleanse the eye thoroughly, and repeat the cleansing as often as necessary—even to the extent of fifty times a day. In addition, use a solution of silver nitrate (5 or 10 grains to the fluid ounce). Make the applications yourself. Take your seat opposite the nurse who holds the child, and place the child's head between your knees so as to hold it securely. Raise the upper eye-lid with the fingers of your left-hand while the nurse pulls down the lower lid with the fingers of her right hand. When the lids are swollen, as in this case, it is difficult to evert them; and it may be absolutely impossible to see the eye-ball. Examine it if possible, as it is important to keep track of the case. When the lids have been opened, briskly paint over the eye, with a camel's hair brush, your solution of silver nitrate. After a minute

or two, neutralize it with a solution of common salt.

For cleansing the eye between the applications, use plain warm water, or mercuric chloride, 1–4000, and keep light cloths, soaked in a cold solution of the same strength of corrosive sublimate, constantly over the eyes.

It will not be necessary to continue this vigorous treatment more than twenty-four hours. You may continue to use silver nitrate (gr. ss to f℥j), but I prefer to change to zinc sulphate (gr. ss–i to f℥j) and put three or four drops in the eye, three times a day. Other methods are suggested, such as syringing out the eye, which may be useful at times when the lids can not be opened so as to expose the eye-ball; but I think you can do just as well with the brush or with absorbent cotton as with anything else.

LETTER FROM BERLIN.

(FROM OUR SPECIAL CORRESPONDENT.)

Prof. Leyden.—Trichinosis of Twenty-seven Years Standing.—Disorders of School-Children.—Maximum Dose of Sulphonal.—A Young Poisoner.—The Bacillus of Musk.—A Monstrous Whale.—Congress of Internal Medicine at Wiesbaden.—Good Specialists must first be General Practitioners.—German Laws to Prevent Deception by Quacks.—Dettweiler on Tuberculosis.—Fibrinous Rhinitis.—Chronic Prostatitis.—Electric Massage.

BERLIN, April 13, 1889.

Prof. Ernst Leyden, of the University of Berlin, celebrated this week his twenty-fifth anniversary as a teacher of clinical medicine. The *curriculum vitæ* of Leyden, Germany's greatest living clinician, is full of interest. He started in Berlin, as all Professors *in spe* do, as a *privat-docent*, but was very soon called to Königsberg, then to Strassburg, and returned to Berlin after an absence of nine years. In Königsberg he worked in conjunction with Recklinghausen and Spiegelberg, and in Strassburg with Waldeyer and Gusserow, who are now both his colleagues at the Berlin University. After Frerichs's death he took charge of what is called the first medical clinic of the Charité. Leyden was the pupil and *protégé* of Traube, the great clinician, and has followed closely in his footsteps. Traube and Leyden can claim the credit of having introduced into Germany experiments on animals in the study of morbid conditions. Leyden studied at the Berlin Military Medical Institute, and counted among his fellow-students such men as Virchow, Helmholtz, Nothnagel, Fräntzel, Schmidt-Rimpler, Reichert and other now famous medical men. Among Leyden's prominent works, the following deserve particular mention: "Observations on poisoning with sulphuric acid" (his doctorate thesis, 1853); "Researches on the sensibility of healthy and sick individuals"; "The gray degeneration of the posterior columns of the spinal cord"; "Acute poisoning with phosphorus"; "The pathology of icterus." His most eminent work was 'the clinic of spinal affections.' Leyden can be regarded as a worthy successor to Frerichs, though many declare that no living physician equals Frerichs even approximately, while others regard Prof. Senator as Germany's most eminent clinician.

Speaking of Prof. Senator, a singular case, coming recently under the observation of this physician, is recalled to my mind. A patient, who had been treated for œsophageal cancer, had died and an autopsy was instituted. The examination showed the entire body crowded with trichinæ. There was not a single fibre of a tissue in which hundreds of the spiral parasite could not be detected; in a single muscular flap, weighing one and two-thirds grains, 280 trichinæ were counted. The clinical history showed that the patient had been a night-watchman, and that in an epidemic of trichinosis which had visited his native place in 1862 he had also become infected, but had recovered again. He attended to his duties uninterruptedly, but complained occasionally of rheumatic pains. The man, therefore, had a case of chronic trichinosis of twenty-seven years standing, which probably has no equal in the literature of this disease.

The German Imperial Government has ordered a special investigation of certain disorders occurring among school-children, believing that there is an etiological relation between the disorders and the modern school methods. First came the investigations in regard to myopia, which had become of alarming frequency, especially in the higher schools of Germany. Prof. H. Cohn, the famous Breslau oculist, was in charge of these examinations, which have not been wholly without success, as henceforth such examinations are to be made at regular intervals throughout the Empire.

Of greater interest were the observations

made on school-children by Dr. Bresgen, of Frankfort-on-the-Main. He found that in many children, who were notoriously inattentive and slow in making head-way, neglected disorders of the ear or nose, such as catarrhs or slight inflammations, could be detected. Dr. Bresgen pointed out that an impeded nasal inspiration caused a pressure in the frontal region, which could readily produce a bad effect on mental development. Such children complain of headaches, ringing in the ears and similar conditions, grow more and more inattentive and lazy. Dr. Bresgen's pertinent reports to the Secretary of Instruction were not heeded until the observations of Prof. Guye, of Amsterdam, confirmed the experience of the German observer. Guye found in adults that nasal catarrhs of long standing and of a neglected character exert a most deleterious influence over the entire mental condition of the patient. He found as results of the conditions mentioned morbid headaches, vertigo, progressive decrease of the perceptive faculties, disinclination and even inability to work. All of these symptoms disappeared after the cure of the nasal affection. Other observers have also confirmed the views and assertions of Bresgen and Guye. As after measles and scarlet fever disorders of the nose and ear are of especially frequent occurrence, it seems the duty of the teachers or rather, of a special school physician, to attend immediately to these conditions. Great mental disturbances can in this way be prevented by a timely and trivial attention.

It has been left to a workingman to answer satisfactorily the question of the maximum dose of sulphonal, regarding which therapeutists have hitherto not agreed altogether. Hans Knickebein, a workingman engaged with Riedel and Co., the Berlin manufacturers of sulphonal, decided to exhibit this hypnotic to his spouse, in order to alleviate her insomnia which, of course, is rather troublesome to a husband accustomed to coming home late, as was the practice of Hans. He consequently took home a good quantity of the drug, but, as a conscientious physician, he decided to determine previously the proper dose on himself. He took two tablespoonfuls of the salt. The effect of the drug was good; the man slept *ninety hours*, awoke and slept again for *twenty-four* more hours. He had taken *eight drachms* of sulphonal, which had produced a sleep of one hundred and fourteen hours' duration, but, fortunately, no other ill effects.

A half-grown girl, 14 years old, was recently tried before the Berlin Courts for three attempts to poison children with oxalic acid. In two instances the girl had mixed the poison with the milk intended for the children on whom she waited, and in the third instance she had poured the acid into Hungarian wine which she sent to the parents of her intended victims by mail, as if coming from their family physician, after previous notification by a postal card. The special interest attaching to the case is the fact that no reason whatever could be assigned to the criminal attempts of the young poisoner. Possibly we have to deal here with a new type of mental aberration, which could be properly termed toxomania.

There are about twenty-five Japanese students attending the medical schools of Berlin, and it has been noted with satisfaction by the University authorities that nearly all of them have shown special inclination and aptitude for original work and researches. Dr. Ritasato has just published an interesting report on a new bacillus, belonging to the class of *fuxisporium*, which has the peculiarity of producing the smell of musk. Hitherto we knew only of bacteria which produced special colors or poisons or of such as were luminous, while a smell-producing bacterium was never heard of. The musk-bacillus was first discovered in an infusion of hay, and can be cultivated on various culture-soils, especially on rice and potatoes. Its cultures are at first reddish, then brick-red, and always give out the distinct and characteristic odor of musk. Dr. Ritasato's name is already known in medical literature through his contributions on the cholera-bacillus.

The sensation of the day in Berlin is a monstrous whale, which however has not been caught in the Spree, but has been transported to Berlin from a Danish island, where it had stranded and perished of hunger. The whale on exhibition belongs to the order known as *mysticetes*, which has barbs on the upper jaw instead of teeth, and to the family of *balænoptera musculus*. The stupendous business of embalming the monster has been undertaken by Dr. Wickersheimer, of Berlin, in connection with a Danish chemist. The height of the animal is sixteen feet, its length sixty-four feet. The number of barbs is about three hundred and seventy-five. This variety of whale, in spite of its gigantic proportions, swims with ease and a rapidity, it is said, fifty miles an hour, so that for a trip around the world

about twenty-five days would be sufficient. The animal's intestines, which were taken out in Copenhagen, weighed about twelve thousand pounds. It is hoped to preserve the animal for a long time, and possibly ultimately to mummify it. From Berlin the whale is to be taken to Vienna.

The annual Congress of Internal Medicine, at Wiesbaden, is always regarded as an important event by the German profession, and is sure to attract many clinicians and teachers of fame and a multitude of practitioners from all parts of the Empire. Among the host of notable medical men present at the Congress this year, were Liebermeister, of Tübingen; Leube, of Würzburg; Vieror, of Leipzig; Jürgensen, of Tübingen; Curschmann, of Leipzig; Rosenthal, of Breslau; Bäumler, of Freiburg; Ebstein, of Göttingen; Fürbringer, of Berlin; Immermann, of Basle; and Petersen, of Copenhagen.

The Congress was opened on April 15 by an address by Liebermeister, who spoke of the aims and purposes of the annual discussions on internal medicine, as originally planned by Frerichs and Leyden, the founders of the Congress. The expanse of specialties, Prof. Liebermeister said, has of late been enormous, and, while it testifies to the ever progressing development of medical science and practice and as such is to be welcomed, it is not devoid of serious danger. The young physician selects, possibly already during his collegiate career, frequently a specialty and devotes his time and attention to the great neglect of internal medicine and general practice. No physician can ever become a specialist of note, unless he is a good general practitioner, and to be a good general practitioner means to have devoted many years of studious care and hard work to general practice. Internal medicine is the trunk of all medical practice, and to its furthering and fostering German practitioners have decided to meet annually in beautiful Wiesbaden, to exchange their views and to discuss the recent advances of their art.

Liebermeister, in the course of his felicitous address, complimented the German Government on its constant endeavors to protect both the public and the regular practitioners from the unscrupulous devices of patent medicine men and quacks. The public, Liebermeister said, can expect from the Government the same protection regarding their bodies which their purses receive with respect to the lottery and confidence men. For the sake of a better understanding of the protection German citizens receive in regard to medicine and treatment, your correspondent begs to explain that no patent medicine whatever, which consists of more than one constituent, is allowed to be advertised by a paper or by any other means. The Government, besides, publishes in all daily papers a precise analysis, including medicinal worth and actual cost, of all remedies sold by patent medicine venders. The following advertisement, for example, can be found in all papers: "Attention! Druggist H. H. Darner, of Rochsburg, formerly a carpenter, sells a remedy, under the name of 'H. H. Darner's Safe Dyspepsia Cure,' at the price of three marks (75 cts.). The alleged remedy consists of (here follows an analysis of the ordinarily very simple composition). Medicinal value, none; but it may under certain conditions be injurious. Actual cost, three pfennigs (four-fifths of a cent). The public is warned against buying the above article. V. Richthofer, President of Police, Berlin. No physician, besides,—and this refers to every other sign—is allowed to hang out a sign unless the police have given, after careful investigation, their sanction. (How would it do to treat similarly all pretenders in the medical line in America?)

The most interesting paper of the Congress, and one which elicited most valuable discussions, was that of Dr. Dettweiler on Tuberculosis. The researches made some time ago by Dr. Cornet, of Reichenhall, in the Hygienic Institute of Berlin, under the directions of Prof. Koch, have thrown a new light on the mode of propagation of tuberculosis. A consumptive person, Dr. Dettweiler said, *per se* is quite harmless as far as contagion is concerned, provided his sputa are at once thoroughly disinfected. Tuberculosis can, in his opinion, based on numerous and careful bacteriological and clinical observations, be propagated only through the sputum of the patient. A tubercular patient who uses either a handkerchief, or an ordinary spittoon, or spits on the floor, can communicate the disease to his neighbors, and the atmosphere surrounding such a patient is impregnated with the pathogenic bacilli. After the sputa, which have been thrown into an ordinary spittoon, on the floor, or into a handkerchief, have become dried, the bacilli reach the atmosphere, mingle with the fine atmospheric dust and are disseminated at large. They may settle on walls or pieces of furniture, and may for a long period retain their vitality. The question arises, what can we

do to check the propagation of the disease under this new etiological light? The answer would be: very little without direct legislation on the subject and strict enforcement of the ordinances to be passed eventually. The point to be reached is evidently a compulsory disinfection of either all sputa —which of course is impossible—or, at least, of the expectorations of tubercular persons, which is also a matter of great difficulty. In countries with a powerful and well-concentrated police apparatus the prospects of success or, at least, of improvement in the direction indicated are somewhat more hopeful than in a free country such as America. Legislation should, according to Dr. Dettweiler, enforce the placing of spittoons filled with an antiseptic solution in all public places, hospitals, schools, etc., and see to the instruction of the school and public at large on the subject. Tubercular subjects, besides, should be compelled immediately to render their sputa antiseptic. To facilitate this desideratum, Dr. Dettweiler has constructed an ingenious little antiseptic pocket-spittoon for the permanent use of consumptives. The little instrument in question has two openings; the upper one serves for emptying the sputum, and has a screw lid which, as in pocket ink-stands, prevents the flowing out; and the lower one serves for the antisepsis and elimination of the sputum. In this manner both the hygienic and æsthetic requisites could be fulfilled.

The remarks of Dr. Seifert, of Würzburg, on fibrinous rhinitis proved also of considerable interest. The speaker illustrated the subject by microscopic specimens. The affection occurs, Seifert said, both in a primary and in a secondary form; the former is principally found in children, and the latter is extremely rare. To call the affection *rhinitis crouposa* Seifert regards as little commendable, all the more as the line of demarcation between croup and diphtheria is not yet accurately fixed.

Dr. Posner, of Berlin, read a valuable paper on the diagnosis and therapeutics of chronic prostatitis. This affection, Posner maintained, is very often overlooked and mostly difficult to diagnosticate because of its symptoms, which are chiefly internal ones, and because a local examination is frequently neglected. It is not a rare occurrence to have a patient treated for years for sexual disease, until its prostatic character is revealed. Within a rather recent period, the speaker said, the diagnosis of chronic prostatitis has been materially facilitated. Seifert referred then to his own researches on the nature of the prostatic secretion, which allowed of a ready determination of the disease.

The paper of Dr. Nordhorst, of Wiesbaden, on electric massage, was of special interest. In order to utilize in chronic affections of a traumatic and rheumatic type simultaneously, the beneficial action of massage and of the constant current, Nordhorst has constructed a massage-electrode (in the form of a little roller) which not only conducts the current, but also as an instrument of massage is far superior to the hand. The electrical massage is performed in exactly the same manner as an ordinary massage. The advantages of an electrical massage are not merely of a theoretical nature but have also been practically confirmed. Of 208 cases treated with this form of massage all could be discharged as either completely cured or materially improved. Precisely the same disorders as are eligible for ordinary massage are suitable for electric massage. It is, however, especially indicated in all rheumatic affections of joints, muscles, nerves and tendons. In migraine this treatment is also of value. The results obtained with the electric massage in the Wilhelms Heilanstalt, of Wiesbaden, harmonize with the speaker's experience: Of 33 grave and inveterate cases, treated for months with massage and electricity without success, 23 were cured by the combined treatment. Nordhorst then referred to a pamphlet entitled "Therapeutic Success of Electrical Massage," in which he had embodied all pertinent information.

Prof. Liebermeister closed the Congress, which he regarded as the most successful one of all Wiesbaden meetings, both as regards scientific value and also as regards general attendance. The Congress had been visited by 300 physicians.

—Dr. Pinel, of Paris, according to the *Electrical World*, has succeeded in hypnotizing several subjects by means of the phonograph. All the commands given through this channel were as readily obeyed as those uttered directly, and "suggestions" of every possible sort were as effectually communicated through the medium of the machine as if made *vivâ voce*. The conclusion deduced by Dr. Pinel is that the theory of a magnetic current passing from the operator to the subject is entirely baseless, and that the real cause of the phenomena of hypnotism is nervous derangement on the part of those subject to them.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE AUTOPSY ON MR. BISHOP.

The daily papers all over the United States have during the past week contained a great deal about the autopsy made upon Washington Irving Bishop, who was widely known as "the mind-reader." Mr. Bishop died suddenly in New York, with no relatives at hand. Within six hours an autopsy was conducted by a pathologist who was called in for that purpose by the attending physician, and soon after the story was started that, when this was done, the subject was not dead, but merely in a trance.

Nothing could be more calculated to excite widespread notice,—and it is not surprising that a judicial investigation has been begun by the Coroner of the city of New York to get at the facts in regard to the case.

Medical men will be slow to believe that any pathologist of experience could commit the horrible blunder of opening the body of a living person. It is not to be disguised however that there would be some risk in making an autopsy within six hours after the apparent death of a person of an intense neurotic nature—like Mr. Bishop—who had been in vigorous life but a few hours before, and who was subject to cataleptic attacks, unless more precautions were taken, to be sure of the fact of death, than are needed in ordinary cases. It is not impossible that the condition of so-called trance should deceive those who are unfamiliar with its manifestations, or not on their guard against the possibility of its occurrence.

But in the case of Mr. Bishop, the physician who had the autopsy made was one who had known him for years and who was aware of the fact that he was said to have had periods of trance during the past; and he, as well as the pathologist, may be presumed to have been acquainted with the phenomena of this condition.

Besides this, if they had made the mistake with which a grief-stricken mother has charged them, they could not have been in doubt in regard to the matter as soon as they opened the thorax and abdomen of the subject. In the thorax they would have found the heart beating, and in the abdomen the intestines would probably have manifested vermiform contractions under the stimulus of the air or the mechanical conditions of the operation.

But, with these and other means of knowing what they did the physicians who conducted the autopsy declare that there were no signs of life in the body; and they do this with the manner of men conscious of being right, and not of men endeavoring to hide an appalling blunder.

For these reasons, we think no medical man will hesitate to accept their statement, or fail to sympathize with them as they pro-

test against the clamor excited by the horrible suspicion which has been raised in the minds of the general public.

There is another phase of this occurrence which is not so easy to see the end of just now. This concerns the right of the medical men to make an autopsy without the consent of a near relative. At present they have been placed under heavy bonds to answer at court, and their rights—or error—will soon be decided according to the law of the State of New York. The law in regard to autopsies is not uniform or clear in this country, and the physicians who made one on the body of Mr. Bishop may have committed a technical breach of the law in doing so. The attorney employed by Mr. Bishop's mother asserts that they have committed a misdemeanor; but they can no doubt get plenty of lawyers to assert that they have not, and it will be interesting to see what the Court will say. Meanwhile other medical men may take warning from the annoying predicament in which these medical men are now placed, and make sure, before they undertake any autopsy, that the subject is certainly dead and that they have legal authority to act.

VACCINATION AND SMALL-POX AT SHEFFIELD.

The opponents of vaccination for small-pox will not receive much comfort from reading the report of Dr. Barry to the Local Government Board on the recent outbreak of small-pox at Sheffield, England. The London correspondent of the *New York Medical Journal*, May 11, refers to the anti-vaccination agitation which is in progress in England, and to the jubilation over the fact that the English Government has granted the request made by these agitators for a Royal Commission to investigate the working of the vaccination acts. It is noticeable, however, that they have made no use in the debate of the facts contained in Dr. Barry's report. The latter dealt with 6,088 cases, of which 590 were fatal. Dr. Barry investigated the circumstances of every fatal case, of every case alleged to have occurred in children under ten who had been vaccinated, and of every case alleged to have taken place after previous small-pox or re-vaccination. He found that the attack-rate of the vaccinated children under ten was 5 in a thousand, and that that of the unvaccinated children of the same age was 101; the death-rate of the vaccinated children under ten was 0.09; and that of the unvaccinated 44. The experience in reference to those over ten was similar. For every 100,000 of those twice vaccinated, there were 8 deaths; of those once vaccinated, 100 deaths; and of the unvaccinated, 5,100 deaths. The outcome of the report was that, if the vaccinated children had been attacked at the same rate as the unvaccinated, there would have been 7,000 attacks in place of 353 and 3,000 deaths in place of 6; or, up to the conclusion of the epidemic, there would have been 4,400 deaths in place of 9.

These statistics furnish evidence of a sort which it would not be easy to gainsay; and they seem to justify the practice of vaccination, in spite of the theoretical objections which are sometimes raised against it.

THE HYMEN AS AN EVIDENCE OF VIRGINITY.

The presence of an intact hymen has long been regarded by mankind in general as a proof of virginity, and its significance has been said, by certain writers, to have led to the adoption of the crescent as the symbol of Diana, by the Romans, who were supposed thereby to suggest, in a figure, her unapproachable chastity. This belief is more interesting as a sign of the disposition some men have to discover obscure allusions to sexual matters in the pictures and statues of the ancients, than valuable as a mark of real erudition; and it is not generally held by mythologists. But the belief that an unruptured hymen is good evidence that its pos-

sessor has never indulged in sexual intercourse is almost universal among the laity, and is apparently held by many medical men of reputation. Meymott Tidy, in his work on Forensic Medicine, says that of late years Barnes, Oldham and Tyler Smith have sworn to the fact of females being *virgines intactæ*, chiefly on the ground of the integrity of the hymen; and he himself thinks a physician who finds a hymen absolutely unruptured, and no signs of pregnancy, is justified in giving a positive opinion as to the existence of virginity.

Notwithstanding the apparent absence of qualification in these statements, they can hardly be supposed to have been intended to mean exactly what appears on their face; for men so well informed must have known that they are subject to exception. Medical literature contains many illustrations of the fact that sexual intercourse may, in some cases, be indulged in repeatedly without laceration of the hymen, and that labor may be obstructed by the presence of the very condition which has been presumed to be a mark of virginity.

Very recently, in the *Transactions of the Royal Academy of Medicine in Ireland*, Dr. R. J. Kinkead, of Galway, reports a case in which he found labor obstructed by an unruptured hymen, the opening of which was no larger than the diameter of a crow's quill, and two other cases coming under his own observation, in which intercourse had taken place without laceration of this membrane, one of the subjects being a young woman who had been seduced when seventeen years old and who had led the life of a prostitute for about seven years afterward.

These cases indicate that the presence of an unruptured hymen can by no means be regarded as a proof of virginity. It may be so regarded in most cases, but not in all; and a medical witness called upon to testify as to the significance of this condition would make a serious mistake if he asserted that it furnished anything more than presumptive evidence of the chastity of the subject.

REPLACING THE BONE AFTER TREPHINING.

The custom of dividing the button of bone removed by the trephine and placing the fragments in the opening is now more or less general, and seems to be of use in securing a bony closure of the defect in the skull instead of a membranous one. It has been proposed, also, to replace the entire button, and the *Deutsche med. Wochenschrift*, March 28, 1889, contains a report of a case to the Freie Vereinigung der Chirurgen Berlins, in which Prof. Küster adopted this method with apparent success. The operation was an exploratory one. The patient had months before had a severe wound of the scalp caused by a blow and followed by symptoms of brain disorder. Splintering of the inner table of the skull was suspected, and the skull was trephined. No splintering was found, so Küster did not open the dura mater. He replaced the button of bone entire, and it grew fast to the skull.

Whether the union will persist or not, and whether the piece of bone will remain without necrosis or absorption after months or years have elapsed, cannot be certainly predicted; but at the time when Küster exhibited his patient the result was all that could be desired. So far the replacing of the bone may be approved, although it is by no means clear that the a bony covering to an opening made with a trephine is so superior to the usual membranous covering as to make it worth while to take the trouble and incur the risks to primary union which are inseparable from the method of replacing the button entire or after its division into small pieces.

THE CHICAGO INSANE ASYLUM.

Just now, when the Department for the Insane of the Philadelphia Hospital is under fire in regard to the treatment of its inmates, it is interesting to note that the authorities of the Cook County Insane Asylum, Chicago, are in a somewhat similar position before

the public. They have been put in a very unpleasant position by recent statements of Dr. Clevenger, who was formerly a member of the medical staff of the Hospital. According to these statements the patients are not only shamefully neglected and allowed to become very unclean, but they are also cruelly treated. This disgraceful state of affairs is attributed by Dr. Clevenger to political jobbery.

Whether the charges made against the Chicago Insane Asylum are true or not, they indicate that such practices as he alleges occur there, are likely to develop in any charitable institution which has been allowed to fall into the hands of persons who manage it for political purposes or from mercenary motives.

MEDICAL SOCIETY OF NEW JERSEY.—The one hundred and twenty-third annual meeting of the Medical Society of New Jersey will be held at the Coleman House, Asbury Park, N. J., on Tuesday and Wednesday, June 18 and 19, 1889. An interesting and instructive programme has been provided. A reception will be given to the members of the Society on Tuesday evening.

—The Philadelphia *Ledger*, May 2, 1889, says that the French Council of State has concluded the examination of a series of public administrative rules applicable to the various modes of burial and cremation. With regard to the burning of the bodies of the dead, no apparatus for cremation is to be made use of without authority from the Prefect, who will grant it after consultation with the Hygienic Council. Every burning of a body is to be authorized by the Registrar on an application from the family, and the production of a certificate from the doctor who attended the deceased that death was due to a natural cause, or, in the absence of this, a report of the inquiry conducted by the municipal doctor. A report will be drawn up recording the reception of the body and its incineration, which will be transmitted to the municipal authority. The ashes will not be allowed to be deposited, even provisionally, anywhere except in places of burial regularly established, or to be removed without consent of the municipal authorities.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

THE INSANE IN FOREIGN COUNTRIES. AN EXAMINATION OF EUROPEAN METHODS OF CARING FOR THE INSANE. BY THE HON. WM. P. LETCHWORTH, President of the New York State Board of Charities. 8vo, cloth, pp. xii, 374. New York and London: G. P. Putnam's Sons, 1889. Price, $3.00.

This magnificently illustrated and handsomely printed book is one which is calculated to be of great interest and value not only to all persons connected with institutions for the care of the insane, but equally, we believe, to all humanitarians and persons interested in the history of medicine.

The introductory chapter contains a brief historical sketch of the treatment of the insane in various countries from the earliest times to the present day. Then follow chapters devoted to the lunacy systems of England, Scotland, and Ireland, and to representative institutions of these and Continental countries, and a chapter each is given to the remarkable insane colony of Gheel and to the noted asylum at Alt-Scherbitz, near Leipzig, which latter illustrates the combined excellencies of a colony and a hospital.

The final chapter presents a *résumé* of the author's observations and his conclusions drawn from them. Based upon the results of his inspections of foreign and American asylums and of his own ripe experience in the supervision of the defective classes of New York State, Mr. Letchworth offers his views as regards the selection of sites and locations of asylums, the kind of buildings to be provided, the questions of sewage disposal, water supply, protection against fire, the laying out of the grounds, the furnishing and decoration of wards and rooms, the difficult problem of the disposition of the acute, the chronic, and the criminal insane, the practice of restraint and the amount of liberty that may be granted, the character of the attendants to be chosen, the religious exercises, amusements, employments, dress and clothing, visitation and correspondence of patients, *post-mortem* examinations, the question of voluntary admission, the methods of admission and discharge, and the value of summer resorts. All of these subjects are treated clearly and explicitly. Besides these, the author gives his personal views respecting the insane in poorhouses, local or district care of the insane, state care, the boarding-out system, state supervision, and kindred topics.

The book is beautifully printed and richly illustrated with engravings and heliotype reproductions of plans of buildings and asylum interiors and pictures of historical interest, and is as creditable to the publishers as to the author.

THE ILLUSTRATED OPTICAL MANUAL OR HANDBOOK OF INSTRUCTIONS FOR THE GUIDANCE OF SURGEONS, ETC. BY SURGEON-GENERAL SIR T. LONGMORE, C.B., F.R.C.S., Professor of Military Surgery at the Army Medical School, etc. Fourth edition, enlarged and illustrated by 74 figures from drawings and diagrams by Inspector General Dr. Macdonald, R.N., F.R.S., etc. London and New York: Longmans, Green & Co., 1888. Large 8vo, pp. xx, 239. Price, $4.50.

There is such a marked contrast between the general appearance of the present edition of this

manual and the first, which appeared nearly twenty-three years ago, that we are tempted to read the new work—which practically it is—most thoroughly and carefully.

As we reach the closing pages, we feel convinced that our labor has been both pleasant and instructive. Physiological optics have been brought to date; methods for the determination of refractive and accommodative error are accurately described in detail; and excellent wood-cuts have been discriminately distributed throughout the text. The errors, as for instance, the designation of Retinal Shadow Test by the incorrect term Keratoscopy; and the coinage and use of curious and meaningless technicalities, may all be excused. The author is to be congratulated upon his endeavors, as the contents are both valuable and instructive, not only to the Military and Naval Surgeon, for whom the volume is especially intended, but also to the general and special surgeon whose duty it may be from time to time to obtain adequate knowledge upon such subjects. It is to be regretted that our English friends will persist in giving their American cousins a binding that is only adapted for their own climate, and which breaks and splits upon the slightest usage.

LA MORT PAR LA DÉCAPITATION. PAR LE DR. PAUL LOYE, Preparateur du Laboratoire de Physiologie de la Sorbonne, Paris, etc 8vo, pp. xii, 285. Paris: Bureau du Progrès médical, 1888.

In this curious volume, Dr. Loye discusses the question whether or not consciousness lasts after decapitation. By a number of careful observations and ingenious experiments, he has been led to the conclusion—in which we think the reader will certainly follow him—that in man consciousness is immediately terminated by decapitation, although in dogs manifestations of reflex excitation, due probably to deprivation of oxygen in the brain, last for some time, unless the knife has been made to pass through the medulla oblongata.

Dr. Loye's book contains very much that is of interest to the physiologist, as well as to those who may discuss the question of the best mode of executing criminals. In France decapitation is regarded as the best method of execution, and the conclusions of this book support this opinion.

In this country, the attempt to make the death penalty as free from horrors as possible has led one state to adopt the method of execution by electricity. It is not to be expected that Guillotining will ever be adopted here; but we think it would be a more rational and decidedly more merciful method than hanging, or even the mode now legal in New York.

Literary Notes.

—The *Annales Médico Chirurgicales* with its May issue assumes the title of *Annales de thérapeutique Médico-Chirurgicales*. It will be published monthly under the direction of Dr. Constantin Paul, Dr. L. Duchastelet still continuing in the position of Editor in Chief.

—Dr. Desesquelles has recommended as a topical antiseptic a mixture of one part of powdered β naphthol with two of powdered camphor. The two are triturated together, dry, until they unite to form a colorless or creamy liquid.

Notes and Comments.

Dr. Macewen on Aneurism and Epilepsy.

At a recent meeting of the Glasgow branch of the British Medical Association one of the most interesting demonstrations was that by Dr. Macewen. He showed, first, a man who had been subject to epileptic seizures for many years. A year ago Dr. Macewen removed a tumor from the cerebrum, with the result that the seizures have entirely ceased. The second subject demonstrated was a new method for the cure of aneurism, in which the object of the surgeon is to produce in the cavity, not blood-clot, but a "white thrombus" of connective tissue. This is accomplished by passing needles into the aneurism in such a way as to pass through one wall of the sac and just to touch the lining of the opposite wall; the current of blood causes an oscillation of the needle and a number of fine scratches on the inner surface of the endothelium, irritating it slightly and leading to the proliferation of leucocytes. From these connective tissue is formed, and a white fibrous mass develops on the inner surface of the sac. The irritation is repeated at intervals of days, the needle being introduced at different spots. The result is the formation of a strong layer of connective tissue, which is firmer than red clot, and involves no danger from embolism.—*Lancet*, March 2, 1889.

Yellow Fever in Brazil.

The extent of the yellow-fever scourge in South America has been only partly known to us. In Rio de Janeiro the mortality has been severe, but recent despatches show that it has declined. At Santos there has been no abatement; in that city of 14,000 inhabitants there have been more than five hundred deaths in a single month—which is equivalent to an annual death-rate of 420 per 1000, from that one cause. At Campinas the streets are almost deserted, and the poor are making appeals for aid and succor. The corps of nurses at Santos has done admirable work, and several members of the Italian White Cross Volunteers have died at the post of duty. The mercantile community at Santos has suffered greatly and it is stated that there is not a business house there that has not lost some of its employés. There is a government Committee of Relief with considerable means at its disposal.

Hemorrhagic Malarial Fever.

Dr. W. C. C. Stirling, of Weaver, Texas, says in the *Atlanta Med. and Surg. Journal*, April, 1889, that hemorrhagic malarial fever is quite common in Texas on the creeks and rivers. Its distinguishing feature is hæmaturia. It has been called hæmaturic malarial fever, and is known in the malarial localities as "black jaundice" and "swamp fever." A great many practitioners, he says, give it the name black jaundice, on account of the dark, black urine and yellowness of the skin and eye-balls. Dr. Stirling prefers the term hemorrhagic, as the hæmaturia is accompanied by hemorrhage in other situations. Malaria is not a poison inducing hemorrhage. The most experienced and accurate observers of malarial affections concur in the opinion that malaria establishes the hemorrhagic diathesis only through changes effected in the human economy by its prolonged influence.

The late Prof. S. M. Bemiss, of New Orleans, classes the morbid conditions of malarial fever with its tendency to hemorrhage as follows: First, the blood-changes of chronic malarial toxæmia so alter the consistency of that fluid as to favor the occurrence of hemorrhage. Second, the long persistent states of malnutrition in chronic malarial cachexias produce textural weakening of the vascular walls and increased liability to their rupture. Third, the increased blood-pressure put upon the vascular walls by passive congestion during a malarial paroxysm. The hemorrhage generally takes place in the kidneys, but also takes place in other situations, viz., stomach, bowels, nose, gums, and blistered surfaces. Sometimes the hemorrhage is into closed cavities.

After detailing several of his own cases, Dr. Stirling states that all forms of the disease are dangerous, and should be treated promptly. The first important thing is to administer cinchona as early as possible. Drs. Louis and Lynch, of Carroll's Prairie, Texas, assert that quinine sometimes produces the hemorrhage. While admitting that they are old physicians, and have treated a great many cases, the author does not agree with them. He has never seen hemorrhage follow the administration of quinine. He thinks in their cases the hemorrhage would have occurred if the quinine had not been given. Prof. S. M. Bemiss, who practised in a malarial locality for almost a half century, says that he has never witnessed any symptoms following the administration of chincona salts which justified a belief that they increased the hemorrhage.

After administering cinchona in some form, the next thing is to arrest the extravasation of blood, and to sustain the patient's strength. The best hemostatic is chloride of iron. The tincture should be given every two hours in ten-drop doses. Ergot, and gallic and sulphuric acids are valuable remedies to prevent hemorrhage into the stroma of the kidneys and Malpighian tufts. Bitartrate of potassium, he says, acts as a hemostatic by keeping up the flow of urine through the kidneys. For the jaundice there is no better remedy than calomel. It should be given at suitable intervals, until catharsis has been produced. Milk, eggs, and milk-punch, should be given when they are necessary. Enfeebled action of the heart always calls for stimulants. In many cases the danger of the disease is manifested chiefly by the enfeebled action of the heart. Coldness of the surface is an indication for the external application of heat, by means of warm blankets, hot mustard foot bath, etc. Morphine and atropine should be given hypodermically for restlessness, delirium and convulsions. After the interruption of the paroxysm, quinine should be given in tonic doses, and tincture of the chloride of iron in twenty-drop doses after each meal, together with a nutritious diet.

A slow, imperfect convalescence not unfrequently follows a violent attack, and is attended with feeble digestion and muscular and nervous debility. Good tonics that contain quinine, and something to act on the liver, are about all that is needed.

Anatomical Basis of the Phthisical Habit.

Rudolph Frels, of Munich, in his inaugural dissertation, 1888, states that he has studied one hundred bodies in Bollinger's Pathological Institute with reference to the origin of the phthisical habit. He believes that the following anatomical changes should be considered as the basis of the disease: 1. Narrowing of the upper section of the thorax, especially with shortening of the upper sagittal diameter. 2. Smallness of the heart and narrowing of the great arterial trunks, and especially of the pulmonary artery. 3. Disproportion between the volume of the heart and that of the lungs.

Frels makes no attempt to answer the important question as to the cause of these anatomical changes.—*Deutsche Medizinal-Zeitung*, April 4, 1889.

Chloroform as An Internal Remedy.

Dr. Stepp, of Nürnberg, noting the observations of Salkowski on the disinfecting power of chloroform water, determined to make trial of chloroform internally in a considerable number of diseases. It may here be remarked that the use of chloroform in aqueous or alcoholic solution is less common in Germany than in England, where the familiar so-called "æther chlor." forms a portion of a very large number of prescriptions. In gastric ulcer Dr. Stepp gave chloroform (fifteen grains in a five-ounce bismuth mixture) with great effect, and believes this to be due to its disinfecting, astringent, and stimulating properties. In various affections of the mouth and throat—as follicular pharyngitis, catarrh of the pharynx, gingivitis, and diphtheria—washes and gargles containing chloroform proved very beneficial. In one case of severe psoriasis of the mucous membrane of the mouth, which had been unsuccessfully treated by several medical men, chloroform water effected a complete cure. Two cases of pneumonia treated with chloroform did so well that Dr. Stepp means to make a further trial of it in this disease. Perhaps the most encouraging results were obtained in cases of typhoid fever, though only six of these were thus treated. The value of chloroform in some cases of fever was shown some twenty-five years ago in the Dublin hospitals, but it has never come into general use even in Ireland as an antipyretic.—*Lancet*, March 9, 1889.

Voluntary Co-operation of Micro-Organisms.

Binet states in his Psychic Life of Microörganisms that there exist organisms which lead a life of habitual isolation, but which understand how to unite for the purpose of attacking prey at the desired time, thus profiting by the superiority which numbers give. The *Bodo caudatus* is a voracious Flagellate possessed of extraordinary audacity; it combines into troops to attack animacula one hundred times as large as itself, as the Colpods, for instance, which are veritable giants when placed alongside the *Bodo*. Like a horse attacked by a pack of wolves, the Colpod is soon rendered powerless, twenty, thirty, forty *Bodos* throw themselves upon him, eviscerate and devour him completely. All these facts are of primary importance and interest, but it is plain that their interpretation presents difficulties. It may be asked whether the *Bodos* combine designedly in groups of ten or twenty, understanding that they are more powerful when united than when divided. But it is more probable that voluntary combinations for purposes of attack do not take place among these organisms; that would be to grant them a high mental capacity. We may more readily admit that the meeting of a number of *Bodos* happens by chance. When one of them begins an attack upon a Colpod, the other animacula lurking in the vicinity, dash into the combat to profit by a favorable opportunity.

Labor in Occipito-Posterior Positions.

Dr. T. G. Comstock, in a paper published in the *Clinical Reporter*, March, 1889, states his opinions in the following propositions, in which he will be seen to differ from the opinion of the better teachers of to-day:

1. When the occiput does not rotate normally, and it is driven down into the cavity of the pelvis, it has to travel at least three times as far as when it is anteriorly situated.

2. In this vicious position, the whole body of the child is jammed down into the cavity of the pelvis, and this is necessary before the occiput can escape over the perineum.

3. In this position, the occiput is at first forced a downward grade, into the hollow of the sacrum, and then to advance further, it must take an up-grade in order to glide over the perineum.

4. In posterior rotation, as I have stated, the occiput has to travel at least ten inches before reaching the outlet whereby it can escape into the world, and the whole fœtal ellipse (which only measures eleven inches) becomes jammed down into the cavity of the pelvis, and then the uterine power for expulsion is lost, although the pains still continue, and exhaust the mother.

5. One of the most frequent accidents of delivery when the occiput rotates posteriorly is, if the head is delivered in this position, that the perineum is ruptured.

6. When such cases occur, and we cannot deliver with the forceps, I would propose that lateral section of the perineum be made (episiotomy), and then the delivery can be accomplished. After such a proceeding, I should advise that the lateral cuts be closed at once by catgut sutures. Experience has proved that such wounds made by the knife will heal much easier than jagged wounds made in the central line by long pressure of the head producing traumatism.

Bromide of Ethyl as an Anæsthetic.

Dr. Charles E. Diehl, a dentist of Pittsburgh, in the *Pittsburgh Med. Review*, April, 1889, recommends the bromide of ethyl as an anæsthetic in minor but painful surgical operations, such as the opening of abscesses, the dressing of injuries, etc. His own experience with it, however, is limited to dental surgery. Our readers may recall the fact that Dr. Simpson recommended its use in labor, in the REPORTER, September 8, 1888. The advantages Dr. Diehl claims for it are:

1. Its rapid action; two or three minutes will produce complete insensibility to pain. 2. The extreme fugaciousness of its effect; the patient will regain complete sensibility within a few minutes after the inhalations are stopped. 3. Very often there is utter insensibility to pain, yet with full control of the mental faculties. 4. The absence of all irritating properties in the vapor, and the consequent ease with which it is taken. 5. The absence of after-effects, nausea, giddiness, etc., which usually follow ether and chloroform. 6. The harmlessness of the *pure* drug. The author reports ten cases in which he has used it, and says that since July, 1888, he has employed the bromide of ethyl in one hundred cases.

Mercury-Lanolin in Certain Affections of the Cornea.

At the meeting of the Paris Ophthalmological Society March 12, 1889, Darier recommended the employment of mercury-lanolin in certain affections of the cornea. Local inunctions of this ointment, he says, do very good service in diffuse infiltrations of the cornea unaccompanied with symptoms of acute irritation. Certain slight forms of interstitial keratitis, superficial keratitis, and spreading leucoma may be completely cured by this treatment. Hypodermic injections of corrosive sublimate are the only effective remedy in intense parenchymatous keratitis; but if the disease process relapses inunctions of mercury-lanolin are a valuable remedy to make the cornea translucent. These inunctions have both a mechanical action through the massage and also an antiseptic and solvent action. They are employed as follows: A piece of the ointment half the size of a grain of corn is introduced into the lower conjunctival sac upon a pencil, and then moderate massage of the cornea and eye-ball is practised by the thumb applied to the upper lid. The inunctions referred to are employed morning and evening, and are well borne even by children. The mercury-lanolin is composed of equal parts mercury and lanolin; one-fourth part vaseline may be added to make it so that it will keep longer. Darier states that the cornea absorbs the ointment so rapidly that stomatitis has occurred in several patients after using it some time.

In the discussion upon Darier's paper, Abadie stated that in chronic inflammations of the lachrymal sac, with fungosities and fistulæ—a condition frequently present in scrofulous children—local inunctions of iodoform in lanolin in the neighborhood of the lachrymal sack, in addition to general treatment, effected surprisingly favorable results.—*Wiener med. Presse*, April 7, 1889.

Formulæ for the Use of Naphthol as a Local Antiseptic.

Naphthol is much used abroad as an antiseptic. Dr. Charles Éloy suggests the following convenient formulæ for its employment in the *Gazette Hebdomadaire*, April 19, 1889.

The following is for a weak solution:

Naphthol β	gr. xv
Alcohol (60°)	f℥ xxx

It may be used upon hairy regions which it is desired to render aseptic.

A strong solution may be made as follows:

Naphthol	gr. cl–ccxxv
Alcohol (60°)	f℥ xxx

It serves to disinfect denuded cutaneous surfaces.

For injections, the solution should be prepared warm, and subjected to a mild temperature. Before injecting it into serous cavities, therefore, and into abscesses it will be prudent to heat the syringe previously. The following is a formula:

Naphthol β	gr. cl
Alcohol (90°)	f℥ iiss
Water	f℥ iii ℥ v

As a mouth wash, some drops of the following solution may be used in a glass of water:

Botot Water	f℥ ii
Naphthol β	gr. ix

For purposes of friction, camphorated naphthol may be used. This last is obtained by triturating to liquefaction the following:

Pulverized camphor	parts 2
Pulverized beta naphthol	part 1

Influence of Saccharin upon Digestion.

Although saccharin was discovered in 1879, it was not until 1886 that it was introduced into the practice of medicine. It was highly recommended and extensively used in diabetes, until Worms, of the "Académie de Médecine" of Paris, and Dujardin-Beaumetz cautioned against its use and asserted that it materially retarded and injured the digestion. Of late however the subject has been brought up again, and a number of experimenters have been testing the drug. The majority of the results do not coincide with the opinions of Dujardin-Beaumetz.

Dr. Edgar Gans, of Carlsbad, gives the result of a very complete series of experiments and comes to the conclusion that saccharin does not injure the digestion in any way. Saccharin in powder form seems to retard slightly the digestion of albumen, but in solution it—if anything—aids it. A valuable property of saccharin is its ability to retard fermenting processes in the bowels and to prevent rapid decomposition. In one of his experiments, Dr. Ganz partly filled two test-tubes with intestinal fluid, and closed them with a wad of cotton. To the one a small quantity of saccharin had been added. The contents of the test tube without saccharin became highly decomposed and discolored in two days, while that containing it remained the same for over four weeks.—*Berliner klinische Wochenschrift*, April 1, 1889.

Useful Formulæ in Chronic Rheumatism.

Dr. Daniel R. Brower, in a clinical lecture on a patient suffering with chronic rheumatism, fatty heart and fatty liver, published in the *North American Practitioner*, May, 1889, suggests the following formulæ to aid in the removal of uric acid from the system, and to sustain and improve the action of the heart and of the liver:

℞ Lithiæ citrat. . . . . ℥ii
Strychnniæ . . . . . gr. i
Tinct. Strophanthi . . . . . f℥iss
Aquæ Menth. pip. . . . . q. s. ad f℥iv
M. Sig. Teaspoonful before each meal in water.

℞ Aloes . . . . . gr. ii
Pulv. Ipecac. . . . . gr. i
Pulv. Rhei,
Ferri sulph. exsiccat.,
Ext. Hyoscyami . . . . . āā gr. x
M. Div. in capsules No. X.
Sig. One at bed-time.

Uralium, a New Hypnotic.

Gustavo Poppi, of Bologna, very recently made a communication to the Medico-Chirurgical Society of Bologna, upon a new hypnotic, uralium. This is a combination of chloral with urethan. Poppi concludes, as the result of experiments upon animals and men, that the uralium induces sleep more quickly and surely than all the known hypnotics. It occasions, according to him, no change in blood pressure, and has no untoward secondary effects. It is said to have been given with success to patients with heart disease, mental disorders, hysteria, etc., and always with the best results, even in cases in which other hypnotics had failed.—*Wiener med. Presse*, April 7, 1889.

Orthopædic Shop at the University of Pennsylvania.

The shop for the manufacture of Orthopædic apparatus at the University Hospital has been reopened, and a plan has been adopted for permitting it to be used by any of the gentlemen connected with the University, for their charity cases, or for patients in moderate circumstances, upon application to the Clinical Professor, Dr. De Forest Willard, or to either of the Attending Surgeons in the Orthopædic Department. One of these will be in attendance every day from 12 to 1.00 P. M. at the Dispensary.

Unless desired by the attending physician, no control will be exercised over the patient or over the apparatus, except a mere countersign in order to regulate properly the administration of the shop, which will be under personal management. The charge for charity cases will be regulated so as simply to cover the cost of material and labor. For higher class work, nickel plating, etc., a slight advance in price will be made.

Druggists Violating the Law.

The New Jersey Pharmaceutical Association began its annual session in Bridgeton May 22. According to a newspaper report, Chairman Rennells said that he had been advised by Cortland Parker that there was no law prohibiting druggists from selling liquor as a medicine. He further said that Senator Werts advised them to go on selling as heretofore, provided they were selling honestly. A prominent druggist is said to have stated at the meeting that he violated this law every day, and that every other druggist in the State did openly violate it, and that they would continue to do so.

NEWS.

—Dr. Frank Baker has been appointed Assistant General Superintendent of the Life-saving Service.

—The annual meeting of the Association of Medical Superintendents of American Institutions for the Insane will be held in Newport, R. I., June 18.

—It is reported that Dr. William G. Eggleston, who has for several years been a member of the editorial staff of the *Journal of the American Medical Association*, has retired from that position.

—The Iowa State Board of Health, it is reported, has decided that Iowa medical colleges should, after 1891, be required to give a four years' course to secure their graduates admission to practise in that State.

—Dr. Howard A. Kelly, Associate Professor of Obstetrics and Diseases of Women and Children in the University of Pennsylvania, has been elected Professor of Obstetrics and Gynecology in the Johns Hopkins University, at Baltimore.

—Doctors Beecher, Bell and Horwitz, Demonstrators of Anatomy at Jefferson Medical College, have resigned, and Dr. A. Hewson, Jr., has been appointed Demonstrator-in-Charge. Dr. Hewson was Dr. Forbes's assistant for seven years.

—The number of deaths in Philadelphia for the week ending May 25 was 339, which is 81 less than during the preceding week and 31 less than during the corresponding period of last year. There were 5 deaths from scarlet fever, 5 from measles, and 15 from typhoid fever.

—In experiments recently made in France on the elasticity of cork, it was found that disks of that substance, when submitted to a pressure of sixty-six tons to the square inch, were compressed to one-fifth their thickness, and recovered their original dimensions in exactly ten minutes after the pressure was removed.

—Dr. L. G. Hardman states in the *Atlanta Medical and Surgical Journal*, April, 1889, that he has successfully employed hypodermic injections of cocaine in operations upon the horse. The use of cocaine obviates the necessity of throwing the horse, or securing him in other ways which may do him damage.

—The *Medical Age*, May 10, publishes letters from a number of physicians bearing upon the question of the propriety of removing the Medical Department of the University of Michigan from Ann Arbor to Detroit. Many favor the change because there are greater clinical advantages at Detroit than at Ann Arbor.

—The Governor of Michigan has issued a proclamation prohibiting the importation of Texas cattle, or any other cattle raised south of the 36th parallel of North latitude, until the first day of November 1889, except such as are in transit across the State. The latter may be unloaded only at yards designated for the purpose and which are placarded: "For the feeding of Texas cattle only."

—Dr. Hobart A. Hare has been appointed Editor of the *Medical News*, to succeed Dr. I. Minis Hays, who will have charge in future of the *Amer. Journal of the Medical Sciences*. Dr. Hare has been one of the Editors of the *University Medical Magazine*. He is well known throughout the country as an author, and will no doubt maintain the present standard of the *Medical News*. The new arrangement in regard to the *Medical News* goes into operation on October 1.

—The annual meeting of the Maryland State Board of Health was held in Baltimore, May 14. It was resolved to coöperate with other State Boards of Health to secure the passage of a law absolutely prohibiting the transportation of bodies of persons who have died from small-pox, Asiatic cholera, leprosy, typhus or yellow fever, and to compel those forwarding the bodies of those who have died from diphtheria, scarlet fever or any other infectious disease, to prepare and encase them properly, in order that passengers should not be exposed to the dangers arising from the proximity of their baggage to the bodies when the latter are transported in baggage cars.

HUMOR.

MRS. A.—"Isn't that an awful smelling cigar that man's smoking?" Mrs. B.—"Yes; but I can bear the smell of it when I think how much worse it must be to smoke it. Poor man! He deserves our pity rather than our blame."—*Boston Transcript.*

PAT COLE, the Irishman who killed Coombs in a fight some years since in Brunswick, on being arrested by the Sheriff, said: "It was a fair fight, Mr. Officer; if Coombs had killed me I wouldn't have said a word about it."—*Lewiston (Me.) Gazette.*

THE SUSTAINED SUPREMACY

OF

Fairchild's Pepsin,

In ACTIVITY, PERMANENCE and GENERAL EXCELLENCE

Has won for this product a wide use and recognition in all the principal markets of the world.

We guarantee it to be unchangeable, to maintain its activity and quality under all ordinary commercial conditions; it is therefore, by far the most available for the dispensing counter, as well as in the manufacture of every form of pepsin preparation.

Under exactly parallel conditions, with any proper percentage of acidity and with any proportion of such acidulated water to the albumen, Fairchild's pepsin is positively superior to any pepsin known.

It will, under absolutely comparative conditions, grain for grain, digest more albumen than any other pepsin made.

We will be pleased to send samples to any physician who may wish to ascertain for himself the relative activity of Fairchild's pepsin, or to submit it to any practical trial.

Prices and complete information upon application.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

TAIT'S OPERATION FOR PARTIAL RUPTURE OF THE PERINEUM.

BY THEOPHILUS PARVIN, M.D.,

PHILADELPHIA.

PROFESSOR OF OBSTETRICS AND OF THE DISEASES OF WOMEN AND CHILDREN IN THE JEFFERSON MEDICAL COLLEGE.

The operation devised and done by Lawson Tait in an incomplete tear of the perineum, is probably not as well known by the profession in this country as it should be. Mr. Tait's method rests upon a rational basis, and its results have been pronounced by him, after a large experience, most satisfactory. Having had the opportunity of seeing him operate, and having repeated his operation in twenty-two cases,[1] it has seemed to me that a detailed description of the method, aided by suitable illustrations, might be useful to at least some of the readers of the Reporter. A remark just made must be qualified—that relating to the repetition of Mr. Tait's operation; for in one particular, as will be explained hereafter, I have deviated from his method, though really the deviation is not great. Further, in referring to my own operations I shall frankly mention the mistakes that I have made, so that others may be guarded against their repetition.

Mr. Tait's method of operating will first be given in his own words, and his illustrations presented. Then will follow my description of the operations, the description being made clearer by illustrations, some of them drawn from actual cases during or after operation, by Mr. Burt W. Swayze, a student of Jefferson Medical College; and it is believed that by these means as good an understanding of the operation will be given as can possibly be obtained without actually seeing it.

[1] In addition to these twenty-two, I operated last winter on two patients for complete rupture of the perineum, using the method advised by Mr. Tait in such injury. Possibly a description of the operation may be given in another paper.

Mr. Tait[1] says that when the marginal folds of the buttocks are fully drawn asunder in a case of torn perineum, the old tear is displayed by a thin line of cicatrix extending transversely to the axis of the rent, which of course was at right angles to the plane of the perineum. "The healing of the tear has taken another direction altogether, and we have the cicatrix at right angles to the wound. This is, so far as I can think out the question or know the facts, wholly unique in its occurrence. It forms the basis of the principles of the operation which I perform, and that is absolutely the opposite, as I have already said in a correspondence on this subject with Dr. Percy Boulton, of the principle of all denuding operations. The scheme of my operation is to restore the old rent and unite it at right angles to its representative cicatrix; that is, at right angles to the plane of the perineum. In this way, and in this way only, can the perineum be truly restored, and from this operation only can it be hoped that the restoration will stand the attacks of subsequent labors, as a large number of my restorations have done. I do not know of one having been torn a second time.

"Having the folds of the buttocks pulled firmly apart, so that the cicatrix is put on the stretch, I enter the scissors at its extreme end on one side, and keeping strictly to its line, I run through to its other extremity. The incision is about three eighths of an inch deep, and it forms two flaps, a rectal and a vaginal. From each end of the incision it is carried forward into the tissue of each labium for about an inch, and again backward for about a third of an inch, making a wound like this—

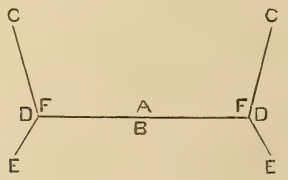

Fig. 1.

The vaginal flap A is held upward, the patient being on her back, and the rectal flap B being turned downward, the angles A F C being pulled by forceps diagonally upward and inward toward the middle line, and the angles B D E being pulled downward and inward. The lines C E thus become straight, and the wound takes this form—

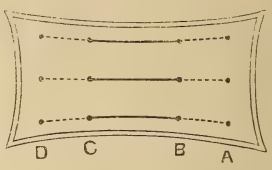

Fig. 2.

"By means of a stout-handled and well-curved needle the silkworm-gut sutures are entered on one side about an eighth of an inch within the margin of the wound, so as not to include the skin, at the dots A. They are buried deeply in the tissue as far as B, and then the needle is made to emerge so as to miss the angle of the wound. The needle again enters at the large dots C, and emerges at the dots B. By thus missing the upper or deep angle of the wound between B and C, the two great and divided masses of the old perineum, which lie in the parallelograms respectively bounded by the lines of large dots A—B and C—D, are respectively adapted. The rectal and vaginal flaps respectively point into the rectum and vagina, and like an old-fashioned flap-valve prevent noxious material entering the wound. The resulting mass of perineum is amazingly large; union is almost inevitable, for I have failed only twice in many hundreds of cases, and then because there had been previous denuding operations, the resulting cicatrix is absolutely linear, and so resembles the natural *raphé*, that in three or four months after the operation it is quite impossible to determine, from the appearance of the parts, that the perineum has ever been injured, for there are no stitch-holes left to tell the story. The pain after the operation is trifling compared to the old method of quilled or shotted sutures. I leave the stitches in for three or four weeks, and take great care that the rectum and vagina are washed out twice daily."

Obviously, as pointed out by Mr. Tait, this operation will prove useful in many cases of rectocele; for, by splitting the recto-vaginal wall to a greater height, we can fill in the triangular space made apparent when the free margins of the rectal and of the vaginal flaps are separated, with the tissues drawn by the sutures from each side, and thus present a barrier to further descent, while at the same time we have lessened the projecting mass; furthermore, by making a horse-shoe separation at the sides of the

[1] This description, given by Mr. Tait, is found in the third edition of H. Macnaughton Jones's Practical Manual of Diseases of Women. London, 1888. The author of the Manual, by the way, strongly endorses the method.

vulvar entrance we can throw the vaginal flap further forward, and thus greatly lessen that entrance. Mr. Tait informed me that he was trying a somewhat similar operation for cystocele, but had not yet brought it to such perfection of method that he was willing to describe it.

Mr. Tait, in his operation, employs for stitches, as has been mentioned, silkworm gut, and the statement made in Vulliet's and Lutaud's recent [1] volume, that silver wire is used, is an error.

The next illustration, Figure 3, shows the operation as begun; the patient is lying upon her back, two assistants, one on each side, while supporting the lower limbs well-flexed upon the body, press with the thumb

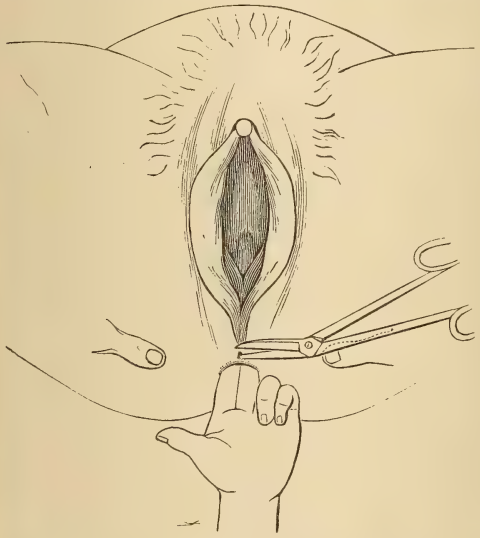

Fig. 3.*

or index finger so as to make the perineum tense; the operator has two fingers of the left hand in the rectum, and enters the scissors about midway in the transverse line to be incised. This beginning at the middle, instead of upon one side as advised by Mr. Tait, is of course not an essential, but it has seemed to me somewhat easier. Next, one-half of the transverse line, as shown in Figure 1 is made, then the other half; the two oblique lines toward the anus are next cut, then those at the vulvar margin, the extent of the latter being longer, as greater lessening of the outlet is required. Finally, the two flaps are by quick clips of the scissors separated to a uniform distance on each side, and to such height as may be necessary.

Figure 4 represents the appearance of the fresh surfaces made by splitting the recto-vaginal wall, the vaginal flap being drawn up with tenacula.

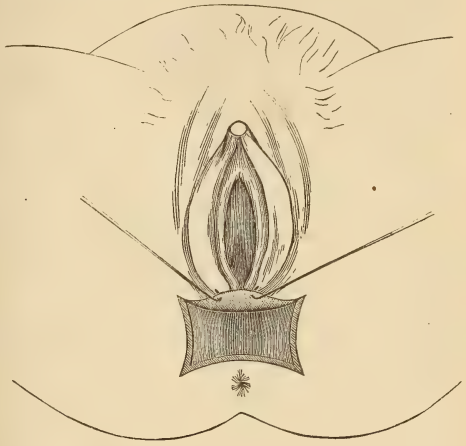

Fig. 4.

The next step is the introduction of the stitches; and the following illustration

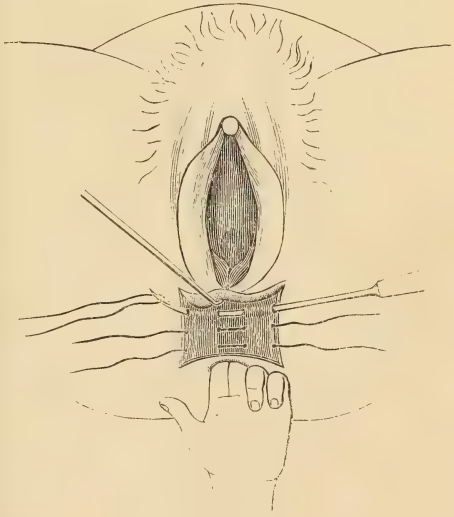

Fig. 5.

shows this process, according to Mr. Tait's method. The operator, still keeping the index and medius of the left hand in the rectum, passes the needle, as has been described, entering on the one side below the skin margin, and first emerging before reaching the apex of the wound, then after

[1] Leçons de Gynécologie Opératoire, Paris, 1889.

* The figure represents the flat of the scissors as parallel to the skin, whereas it should be perpendicular to it, so that a transverse incision will be made.

crossing, thus exposed in the sulcus, reenters the tissues, and comes out upon the opposite side of the raw surface, but does not include the skin; as soon as the eye of the instrument is exposed the assistant upon that side threads the needle with silkworm gut, the operator withdraws the needle, and the suture is in place; then the second and the third sutures are similarly introduced; in most cases these three are sufficient. The wound is now cleansed, and the operator ties the sutures beginning at the one nearest the anus.

In most of my operations, however, I have deviated from Mr. Tait's method in that the stitches have been passed through the skin; for I was not successful in bringing the margins of the skin wound in such close apposition as seemed to me necessary without this inclusion. Nevertheless I mean to try again until the method pursued by me shall be completely that of Mr. Tait, though I confess that I cannot see any harm of at least serious character if the stitches do include the skin in most cases, provided the last stitch be not drawn too tight, the consequence of which will be referred to hereafter.

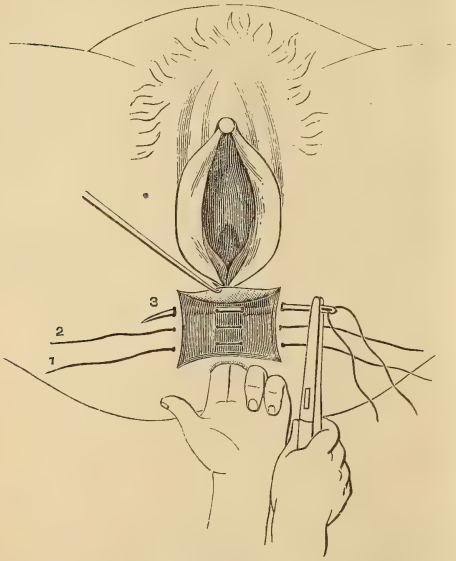

Fig. 6.

Figure 6 represents the introduction of the sutures, a strongly-curved needle and forceps being used, the method which I have generally used.

Fig. 7.

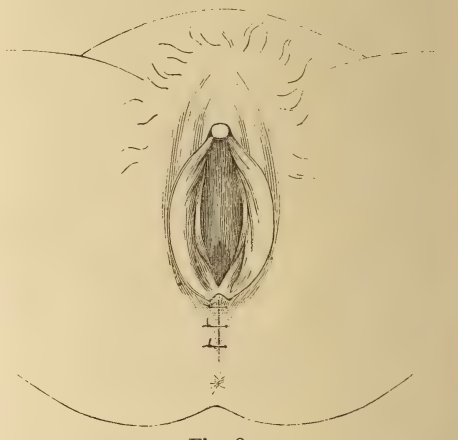

Fig. 8.

Figures 7 and 8 represent the appearance presented after the stitches have been tied, the first when the sutures do not include the skin.

The following illustrations show a strongly curved needle, and the forceps which I have generally used in my operations.

Fig. 9.

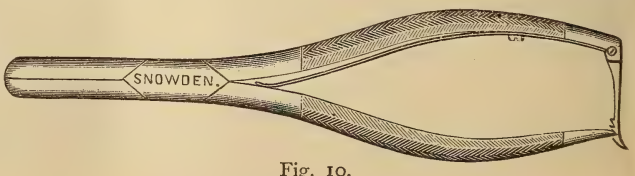

Fig. 10.

In regard to the after-treatment, I believe that washing out the vagina once a day with warm carbolized water, and evacuating the bowels daily by a warm water injection, the patient remaining in bed for the first ten days, are the most important parts. Of course the bladder must be catheterized, if spontaneous evacuation does not occur, and in some cases the bowels not being sufficiently moved by an enema, the use of a mild laxative is indicated. The removal of the stitches I have tried at different periods varying from ten days to three weeks; and my impression is decidedly in favor of late rather than early removal. The newly-united tissues are certainly in no condition to bear any severe strain under three weeks; for in one instance in which I had operated for cystocele,—by denuding an oval surface upon the anterior vaginal wall, and stitching the margins together with silkworm gut, following this operation by a perineal operation, materially lessening the vulvar opening,—three weeks after, in removing the stitches used for the cystocele, I introduced a Sims speculum for the purpose of retracting the perineum so as to expose the stitches, and found that although no great force was used in the retraction, it caused part of the perineal wound to give way. Two stitches were at once introduced, and the result was entirely satisfactory; but I had learned a practical lesson of some value. Nevertheless, if the stitches in the perineum are left much longer than ten days, they are liable to cause some external ulceration, and, more especially if the sutures have been tied too tight, partial cutting through the tissues occurs, with resulting transverse depressions marking the places of the stitches, and elevations in their intervals. From the latter statement a practical lesson is to be drawn: in tying the silkworm gut threads, see that the parts are brought only in apposition, with no wrinkling of the skin, and no strain upon the tissues.

The results in the cases upon which I have operated, have, as a rule, been most satisfactory; and one complete failure and some partial successes have been the result of the error of the operator. The failure occurred in a case operated upon at the Philadelphia Hospital; but the operation was done too soon after the woman's delivery, union did not take place, and the vaginal flap disappeared. In cases of partial success, the cause of the unfavorable result was in drawing the final stitch—that is, the one nearest the vulvar opening—too strongly, so that the lower portion of the vaginal flap projected, forming a tongue-like process; in one instance a week after the operation I found this projection so great, swollen and threatening to slough, that I cut it off, and in two other instances after the removal of the stitches there was an unnatural prominence made by it just at the vulvar entrance.

In some instances, too, immediate union of the entire surfaces brought in apposition did not take place. Possibly the failure may have occurred from the sutures not having been properly introduced or tied, or it may have been from not thoroughly cleansing the surfaces before the sutures were fastened.

The operation that has been described commends itself by its simplicity, by the readiness of its performance, by no tissue being sacrificed, and by its usually immediately satisfactory results. As to the remote results, of course, I can say nothing from personal knowledge, for my first operation was done in October, but I am quite willing to fully accept Mr. Tait's statement as to those results. Vulliet in describing Tait's operation, as he saw it done by Fancourt Barnes, states that it was completed in five minutes; it may be done in less than four minutes if one has assistants who are familiar with their duties. The operation will be found useful not only in uncomplicated partial rupture of the perineum, but also in many cases in which the injury is complicated with rectocele, and may also often be done with advantage after the usual operation for cystocele, supplementing that operation and contributing to prevent recurrence of the accident.

It certainly seems probable that a perineum restored by Tait's method would be much more likely to bear without injury the strain of childbirth than a perineum restored by the common method. Quite recently there was at the Dispensary for Diseases of Women and Children of Jefferson Medical College Hospital a woman who, after having her perineum badly torn in labor, had the usual denuding operation done, but childbirth again had caused as bad a tear as the original one. It is probable such examples are not infrequent. Again, I have been called to a case of labor, in consultation, where the unyielding cicatricial tissue of a restored perineum compelled episiotomy.

In conclusion, and without entering into comparison with other perineoplastic operations, some of which remind one in their diagrams of the many and various curves made by expert skaters upon the fresh ice—an American reviewer of a well-known work upon diseases of women, some years ago

compared one of these marvellous diagrams to a Chinese puzzle—I will only say that it seems to me Mr. Tait's operation has very much to commend it to the profession.

THE INFECTIOUSNESS OF TUBERCULOSIS: A STATISTICAL STUDY.

BY LAWRENCE F. FLICK, M.D.,
PHILADELPHIA.

Because of the confusing and indefinite nomenclature of tubercular diseases, and because also of the incompetence to make a diagnosis of some physicians who practise medicine, the deductions drawn from Board of Health reports cannot be accepted with any great degree of confidence. Nevertheless, with a disease from which there are as many deaths as there are from tuberculosis, we ought at least to arrive at general truths by careful topographical studies of such reports; and it is with the object of throwing some further light upon the question of the contagiousness of tuberculosis that I present this brief paper.

The Fifth Ward of the city of Philadelphia has an area of .321 of a square mile, has a population of about 16,000, and contains in the neighborhood of 3,500 houses. The population consists mostly of poor people, about twenty per cent. being colored, and has in its make up foreigners of every description and nationality; but in no part of the ward can there be said to be great overcrowding.

During the twenty-five years preceding 1888, about 1,500 deaths were returned from the ward under the various terms for consumption of the lungs and bowels, and such other terms as have the word "tubercular" attached or have that word for their basis; and they occurred in about 950 houses, or about thirty per cent. of the houses of the ward. Deaths returned under the heading of "marasmus" and other erroneous names, and which were really due to tuberculosis, are not included in the 1,500; hence thirty per cent. may be looked upon as too low a representation of the number of infected houses. But, inasmuch as deaths from such diseases occur largely in the same houses as deaths from tuberculosis of the lungs—as will be seen from the report for 1888—their exclusion in determining the number of infected houses cannot materially alter the result, and 30 per cent. may be accepted as approximately correct. I have selected twenty-five years as the most remote period by which to determine the infection of a house, for two reasons: First, because a house may retain its infection for a long time by intercurrent cases, which may get well, may move away and die somewhere else, or may die and be returned under some false name; and second, because the more remote the period, the stronger the emphasis on the non-infectedness of those houses which are set down as such.

During the year 1888 there occurred in the Fifth Ward of the city of Philadelphia 103 deaths which may be plausibly ascribed to some form of tuberculosis. Of these, 60 were returned under the various names for consumption; 17 under the heading of marasmus; 7 under that of meningitis, three having the word "tubercular" attached; 5 under that of hæmoptysis; 4 under inanition; 2 each under the names tabes mesenterica and consumption of the bowels; and one each under the name tuberculosis, general tuberculosis, chronic bronchitis, empyema, scrofula, and asthma.

Of the 103, 15 were returned from the residences of undertakers; 3 from the Consumptives' Home, on Spruce Street; one from a lodging room; and one from the Almshouse. Of the cases returned from the residence of undertakers, 11 were cases of phthisis, 2 of marasmus, and one each of scrofula and general tuberculosis. The cases from the Consumptives Home, the case from the lodging room, and the case from the Almshouse, were all cases of phthisis. Four of the cases returned from the residences of undertakers died at the Almshouse, 2 at the Pennsylvania Hospital, one at St. Mary's Hospital, one at St. Joseph's Hospital, one at the Consumptive's Home at Chestnut Hill, and one at Moyamensing prison. Inquiries as to the dwelling-places of these patients before their entry into the hospitals were attended with unsatisfactory results; but some of them at least lived outside of the ward.

Deducting the cases returned from the residence of undertakers, the Consumptives Home, etc.—20 in number, we find that of 103—the number returned from the ward—we have 83 cases which were reported from the residences in which they presumably died. Of these, 44 were cases of tuberculosis of the lung, returned under its various names, 15 were returned as marasmus, 7 as meningitis, 5 as hæmoptysis, 4 as inanition, 2 each as consumption of the bowels and tabes mesenterica, and one each as tuberculosis, asthma, empyema, and chronic bronchitis.

Of these 83 cases, I find that 48 were returned as having died in infected houses—that is, houses in which a death from some form of phthisis, or some disease with the word tubercular attached, had occurred sometime within 25 years; and 35 in non-infected houses—that is, houses in which no such death had occurred within 25 years. Of the patients which died in infected houses, 23 were returned as dying of phthisis under its various names; 10 as of marasmus; 5 as of meningitis; 2 each as of tabes mesenterica, inanition, and hæmoptysis; and one each as dying of tuberculosis, asthma, empyema, and consumption of the bowels. Of the persons who died in non-infected houses, 21 were returned as dying under the names for phthisis, 5 under that of marasmus, 3 under hæmoptysis, 2 each under those of meningitis and inanition, and one each under names consumption of the bowels and chronic bronchitis.

Of the 23 infected houses from which a death from tuberculosis of the lungs was reported, 18 had had a death from tuberculosis in them within 10 years, 14 within 7 years, 12 within 4 years, and 8 within 2 years. Of the 10 infected houses from which a death from marasmus was reported, 9 had had a death from tuberculosis in them within 10 years, 8 within 7 years, 7 within 5 years, 4 within one year. Of the 5 infected houses from which a death from meningitis was reported, 2 had had a death from tuberculosis in them within 10 years, and one within 3 years. Of the 2 infected houses from which a death from inanition was reported, one had had a death from tuberculosis in it within 5 years. Of the 2 infected houses from which a death from tabes mesenterica was reported, one had had a death from tuberculosis in it within one year. The infected house from which a death from consumption of the bowels was reported had had a death from tuberculosis in it within 3 years. Thus it will be seen that out of the 48 infected houses in which deaths from tuberculosis occurred during the year 1888, 32 had had deaths from tuberculosis in them within 10 years prior to 1888.

In only 5 of the 48 cases which were returned from infected houses during the year 1888 was the name the same as that of the person who had died in the house before, and of these, 2 probably bore the relation of husband and wife to the person who had died in the house first.

About the 23 cases of tuberculosis of the lungs which were returned from infected houses, I was given the following information at the houses from which they were reported: First, that 4 of the persons did not die in the house from which they were returned as having died. Upon inquiry, I was able to locate the place of death of two of these, one having died at a hospital and the other having lived and died in an infected house. Second, that 8 of them had consumption before they moved into the houses in which they died. Of 3 of these I was able to discover the former dwelling place, and all three of them contracted the disease whilst living in recently infected houses.

About the 21 cases of tuberculosis of the lung which were returned from non-infected houses, I was given the following information at the houses from which they were reported and by neighbors and friends of the deceased: First, that one of them did not die of consumption, but was reported to have died of that disease from motives of delicacy. Second, that 2 of them did not die in the houses from which they were returned. In both of these I was able to locate the place of death, and in one of them I found that the house was an infected one, that the person had lived there a year, but that he probably had the disease when he moved there. Third, that 7 of them had had consumption when they moved into the houses in which they died. Of 2 of these I was able to discover the previous residence, and in both instances I found it to be in an infected house. Fourth, that 2 of them had been associated with consumptives in their business. In neither of these cases was there any family history of consumption. Fifth, that 5 of them lived in lodging houses, where there was a constantly changing population, and that 3 of these were drinking persons.

This information, I am sorry to say, even meagre as it is, is not very reliable. The fears, suspicions, and prejudices of many of the people from whom I sought it, prevented them from telling the entire truth, and even led them to misstate facts. I give it, however, as I got it, so that every one with the entire picture before him may draw his own conclusions.

Even the data which I took from the Board of Health records I cannot endorse as entirely trustworthy. The custom of returning deaths from the place of burial instead of the place of death, the carelessness of undertakers in giving the numbers of houses and wards, and the indefiniteness of the nomenclature used by physicians, I am sure engendered mistakes which I have

not in every instance been able to correct.

The moving about from place to place of persons suffering from tuberculosis ought likewise to be taken into consideration in drawing conclusions, when the infection of houses, as determined upon mortality statistics alone, forms part of the premises of the argument. To what extent such change of residence alters the actual percentage of infected houses, and consequently invalidates the conclusions based upon the facts and figures I have given, must of course remain an unknown quantity, and must be approximately measured by every one for himself.

In spite, however, of all these sources of inaccuracy, which I have just mentioned, the figures which I have given, bearing upon tuberculosis in the Fifth Ward of this city for the year 1888, point unmistakably to the fact that tuberculosis is not only contagious in the broad sense of that word, but that a house in which that disease has existed remains a centre of infection for an indefinite time. Upon no other theory than this can a rational explanation be given of the fact that, whilst less than one-third of the houses of the ward became infected with tuberculosis during the 25 years prior to 1888, considerably more than one-half of the deaths from tuberculosis during the year 1888 occurred in those infected houses. Inasmuch as there were more than twice as many non-infected houses in the ward, as there were infected houses, we would naturally expect a preponderance of deaths in non-infected houses. Why this great preponderance of deaths in infected houses?

The conclusion that houses once infected by tuberculosis retain that infection for some time, is even more strongly borne out by individual cases than by the aggregate number of cases during the year. A death from tuberculosis occurred in a house on Gaskill street, in 1880. The family moved out and R. H. moved in. He was quite well when he moved there. He was a travelling salesman, and was away from home a good deal, but had his home there. In time he developed consumption, and he died in 1888. L. M. lived in the house in which she died for many years. A person who was no relative of hers died from consumption in the house in 1887. She took the disease in a very acute form, and died in 1888. H. M. suffered from chronic tuberculous diarrhœa, and died from it during the year 1888. During that same year there occurred a death from marasmus in the same house. A death from consumption of the bowels was returned during January, of 1888, from a certain house on Hurst street; a woman who died from phthisis during September of the same year on Lombard street probably contracted the disease in that same house, as she lived there about that same time. During the latter part of 1887, a person died of phthisis in a certain house in the ward; during July, of 1888, a child 9 months old, not of the same family, died in the same house from tabes mesenterica. During the month of September, 1888, there occurred 2 deaths in an infected house in the ward—one from marasmus, in a child one year old, and one from meningitis, in a child 2 years old. The house had had 3 deaths from tuberculosis within recent years, the last one reported being in 1885. In a house on St. Mary street a death occurred from consumption during the latter part of 1887; during July, 1888, a child 17 months old died in the same house from marasmus. A woman is reported to have died from phthisis in a house on Union street during the year 1888, from which no cases of tuberculosis had ever been returned before. The house is a lodging house, and she is said to have taken the disease whilst living there. A man who died in a non-infected house on Spruce street, during the same year, was found to have contracted the disease in that same house about the same time. A death from tuberculosis is returned from a house on Dock street, in 1882. J. C. moved into the house sometime in 1884. He contracted consumption and died in 1888.

These cases are all taken from among those who died from tuberculosis in the Fifth Ward during the year 1888. By going back of that year I could cite from my notes hundreds of equally striking cases, illustrating the infectious etiology of tuberculosis.

Perhaps one of the most interesting lessons to be learned from this inquiry into the relation which the deaths from tuberculosis in the Fifth Ward during the year 1888 bore to those from the same disease during the 25 years prior thereto, is that bearing upon marasmus and meningitis in children. It will be remembered that out of 22 deaths from these two diseases, 17 occurred in houses which had been infected by tuberculosis of the lungs and bowels in adults. It would appear from this that marasmus and tubercular meningitis in children are apt to be concurrent with tuberculosis of the lungs and bowels in adults; that is to say, where

an adult is suffering from phthisis or consumption of the bowels in any house, the children of that house are prone to develop marasmus or tubercular meningitis, and that these diseases are not apt to become centres of infection themselves.

It is somewhat surprising that only 7 deaths were returned from the ward under the heading of meningitis for the entire year, and that really only 3 of those had the word tubercular attached. The number of cases of tubercular meningitis which I meet with in my own practice would lead me to believe that these figures do not correctly represent the relative frequency of the disease, and that in all probability many deaths which are ascribed to convulsions are really due to tubercular meningitis. I have within the last year seen four deaths from tubercular meningitis in children, three of which occurred in houses in which there was a case of phthisis in an adult.

It is greatly to be regretted that our nomenclature of tubercular diseases is not more definite and more uniform than it is; for until it becomes so, statistical and clinical study of the disease will necessarily remain difficult. We cannot hope, however, to make much progress in this direction until the etiology of tuberculosis is settled, and until precise knowledge upon the subject shall be dispensed from every seat of medical learning. It is with the desire of hastening that day that I present this statistical analysis, if I may so call it, hoping thereby to stimulate others to enter this promising field of study.

Many interesting deductions, besides the few which I have made, might be drawn from the figures which I present, and many criticisms made upon the practical operation of our sanitary laws, as a legitimate part of this paper; but it would lead to subjects which in themselves furnish material for extensive papers. I will therefore, for the present, rest content with stating the facts and calling attention to a few of the most striking conclusions which grow out of those facts.

—The question of the origin of the dog has recently been discussed by Prof. Nehring, who believes that it has descended from various still surviving species of wolves and jackals. The latter animals can be tamed, and many attempts to domesticate wolves have been successfully made in recent times. Herr Ronge has so completely tamed a young wolf that it follows him exactly as a dog might do.

HYSTERECTOMY FOR LARGE FIBRO-MYOMA.

BY D. BENJAMIN, M.D.,
CAMDEN, N. J.
SURGEON TO THE COOPER HOSPITAL.

H. M., 30 years old, living in the southern part of New Jersey, came to me on March 24, 1888, suffering from a large abdominal tumor, which she stated that her physicians had called an ovarian tumor. I obtained the following history: Her mother died of erysipelas, one sister died with cerebro-spinal meningitis. The patient's past condition was stated to have been moderately healthy until last summer, when she commenced to lose flesh; at this time there was noticed a slight enlargement of the abdomen, which was attributed to dropsy.

In October, 1887, the patient was examined by a physician, who stated that there was a tumor in the left ovarian region, then about the size of a fist. Two months afterward she was subjected to another examination, and the tumor was found to have increased in size to that of a child's head. No history of any injury to this region could be obtained. Her menstrual flow had been regular, sometimes profuse; it had skipped one month, which she attributed to a cold.

The patient began to suffer from vomiting and constipation, and occasional abdominal pains; these symptoms steadily grew worse, until almost every meal was vomited, and constipation became more and more obstinate, so that powerful purgatives had to be administered, but were losing their effect; symptoms of obstruction were becoming marked. She had lost fifty pounds in weight within a few months, but as she had been previously inclined to be stout, her emaciation was not extreme. The tumor appeared symmetrical and mobile, did not feel so hard as is common with fibroid tumors, nor so soft as a cyst, was not nodular, felt very much like a pregnant womb in the early part of the ninth month. Fluctuation could not be positively demonstrated. The percussion note was dull, except over a small area in each flank. Vaginal examination indicated that the cervix was drawn up; there was an enlargement in Douglas's pouch about the size of a retroverted womb. Examination of the rectum gave no additional information. A flexible urethral sound passed into the os uteri about two inches, taking a forward direction. Before using the sound preg-

nancy was eliminated by examination. A diagnosis of solid or semi-solid tumor involving the womb could be made, but the exact relation of the ovaries to this tumor was not clear. Exploratory incision was advised, with a view of ascertaining the exact relation of the tumor to the pelvic organs, and the possibility of its removal, with the understanding that any beneficial operation that would seem feasible should be proceeded with.

Accordingly, on March 29, the patient was etherized, the usual incision was made in the median line, and the surface of the tumor exposed. The tumor was quite elastic, and of a dark flesh color, and wedged so tightly in the superior straight of the pelvis that only one ovary, the left, which was enlarged, could be reached. As adhesions were slight, the incision was extended upward with scissors—sufficiently to enable the upper part of the tumor to be reached; this part was free, but was in contact with the stomach and liver. The incision was then extended upward and downward sufficiently to enable the tumor to be delivered forward through the abdominal incision.

Both ovaries and Fallopian tubes could then be easily reached, while the large tumor was held upward, out of the abdominal cavity, by an assistant. The pedicle could not be thoroughly examined at this stage. The right ovary was enlarged, was found crowded down into Douglas's pouch, and was enlarged to about the size of a hen's egg, and roughened on the surface. The right Fallopian tube was also much enlarged; the left tube was about double the normal size, and adherent. Both ovaries, and both Fallopian tubes were carefully ligated and cut away. The exact relation of the base of the tumor to the womb could now be clearly made out, and it was apparent that room enough could be obtained above the insertion of the vaginal wall into the cervix to remove the tumor and body of the womb—which was thoroughly and uniformally fused together—without necessarily wounding the ureters, bladder, or other pelvic organ. I then determined to remove the entire tumor and womb, since to return it to the abdominal cavity would have been equivalent to leaving her in almost as bad a condition as before the operation, with respect to the obstruction, and other difficulties which the tumor caused; and at the same time the operation would then be little less dangerous to the patient's life than complete hysterectomy. I then carried the incision downward as close to the pubic bone as the bladder would permit, ligated each of the round ligaments in two places and cut between, applied Koeberle's clamp and cut away the tumor. The stump was at least three inches in diameter. The tumor was about thirty inches in circumference. After all bleeding points had been properly secured, and all clots removed from the abdominal cavity, the bowels and peritoneum was thoroughly washed off by pouring three or four gallons of warm water into the abdominal cavity.

The omentum, which had been lying on a towel, was returned and arranged over the bowels. The pedicle was fixed in the lower angle of the womb, and the incision closed with silk sutures at intervals of less than half an inch. The wound was dressed antiseptically, and the patient placed in bed.

The temperature, which had been normal before the operation, was taken three quarters of an hour afterward, and found to be 97.2°; at 4 P. M., 100.8°. The second day, at 7 P. M., it reached 100.4°, pulse 128, respiration 28. Third day, 7 A. M., temperature 101°; 7 P. M., temperature 101.4°, pulse 116, breathing 24. Fourth day, 7 A. M., temperature 99.4°; 7 P. M., 100.6°. Fifth day, 7 A. M., temperature 99°; catherization was stopped on account of irritation of the bladder. The patient constantly improved without any untoward symptoms, and was discharged in six weeks after the operation. The clamp came off on the twenty-third day. She has not vomited since the operation, has had no pain, and all her functions are normal. The patient states that it is the first time she has felt well for four or five years. She has returned to her home in the country, with rosy cheeks, full of life, and at this date, May, 1889, is in perfect health. She has not been sick a day since the operation, and is glad that she parted with her womb and ovaries.

In determining the value to humanity of the operation of hysterectomy, it is important that all cases should be reported, as I found the literature on the subject so meagre at the time of the operation just described that reliable data could not be obtained in this country. The operation had never, so far as I can learn, been performed in New Jersey; but as hysterectomies are becoming more frequent and successful, ample statistics will soon be forthcoming.

—Dr. W. D. Johnson, who is delivering a series of scientific lectures in San Francisco on the lower forms of animal life, says the oyster is capable of being educated in a limited way.

REPORTS OF CLINICS.

HARLEM HOSPITAL, N. Y.

SURGICAL CLINIC—DR. MANLEY.

Necrosis of Lower Jaw.

The first case for operation was one of resection of the lower jaw on the right side, for necrosis. The patient, a young woman, 25 years old, stated that she had suffered more or less pain along the whole line of the bone for more than three years; that she was never injured in the locality of the disease, and could give no cause for it; that abscesses of large size had formed at different times, between the ramus and ear, and had been evacuated by various physicians. At the time of operation, the patient presented a care-worn, cachectic, and very anæmic appearance, which was no doubt largely due to inability to masticate food, as well as to the want of sleep and the effect of pain and worry.

Dr. Manley, in his opening remarks, said that if he found exfoliation or limited caries, the case could be easily dealt with, as far as operative procedure went; but from what he had learned of the history alone, without examination of the patient, he strongly suspected a necrosis of the whole shaft, and its removal might, in spite of all precaution and care, entail considerable loss of blood.

On opening the larger pus accumulation, the bare and denuded bone could be seen stripped of its periosteum, from the symphysis to above the insertion of the masseter muscle. All the teeth formerly inserted into the true bone had long since decayed or dropped out, except the right central incisor, which was easily lifted up with the finger and thumb.

"In the removal of the inferior maxilla for disease," Dr. Manley remarked, "there are a few points which should be constantly borne in mind, and the neglect of which might not only place our patient's life in great jeopardy, but also leave her in a condition more lamentable than that which we are attempting to relieve. The first is, in a young person, to use every care in preserving the periosteum for the future reproduction of the bone; the second, carefully to avoid wounding Steno's duct, an accident which may leave a fistula difficult or even impossible to close. As this duct passes directly across the ramus of the upper jaw over the masseter muscle, this is no imaginary danger; the third,—and perhaps the most important of all—is to provide against excessive hemorrhage. The numerous great vessels which pass close to the angle—the internal maxillary, facial, transverse facial, and the internal carotid arteries, besides the internal jugular vein and its large tributaries, which drain all the tissues anterior to the ear—are to be avoided as far as possible, though some of them under certain circumstances are necessarily divided. If the bone readily shells out of the periosteum, throughout its whole length, its removal will be a simple matter."

Dr. Manley began his operation by passing a temporary transfixion stitch under the distal and proximal ends of the facial artery, which step cut off one important source of bleeding. An incision was then made in the usual way along the body of the jaw to the outer border of the masseter muscle, when a severe hemorrhage took place, apparently from every direction, but largely from the trunks of some large vessel. The wound was immediately filled and packed with sponges, but yet the blood welled up through and beside them. They were now quickly removed and the common carotid compressed against the cervical vertebræ. This at once checked the arterial admixture, but the hemorrhage still continued with a frightful rush. Clamp after clamp was applied in rapid succession, and the ligature used wherever a visible point of bleeding was observed; but the tissues seemed so soft and friable that the ligatures were of little avail. Dr. Manley now passed the index and middle finger within the mouth of the bleeding patient, along the right side of the buccal cavity, and rapidly pushed the tissues outward. This procedure, while firm pressure was continued, diminished the torrents of blood, which threatened quickly to end fatally if not arrested. The temporary transfixion stitch was again applied above and below, and it immediately arrested all bleeding. The termination of the operation was then completed leisurely.

Double Genu-Varum.

Among other instructive operations at the clinic was one of some interest for the manner in which it was done. It occurred in a case of double genu-varum, in a child two years old. Dr. Manley remarked that, in all cases in young children, when it is deemed advisable to remove the deformity, there is no method yet devised which will take the place of the hand in fracturing the bone, providing this was not too strong.

There is no osteoclast like it, and it should always be preferred to osteotomy, when practicable, as we do not make a slit-wound or create a compound fracture. Besides, he observed, with the osteotome and mallet, owing not only to the different consistency of bone which sometimes exists in the two limbs of the same child, there is danger of applying too much force on the mallet; as what would readily divide one bone would make very little impression on the other. He believes the iron osteoclast to be a dangerous apparatus, as he knows from experience; he says that when the hand will not break a bone, the osteotome should always be used in preference to any other means. In the present case, both bones were readily snapped with the hands; after which the limbs were put in plaster dressings, and the child sent home.

New York Correspondence.

Locomotor Ataxia Treated by Extension—A Rabbit's Cornea Grafted on a Human Eye—How to Treat Chronic Ulcers—Tubercular Ostitis of the Ankle-joint.

New York, May 19, 1889.

Prof. Charles L. Dana, of the Post-Graduate School and Women's College, is using the new treatment of extension for locomotor ataxia on a patient in the Post-Graduate Hospital, and is having marked success. The patient is an expressman from Vermont, 44 years of age. He is married, the father of two children, and his personal history is excellent. His father died of rheumatism. His case is a typical one. Two years ago, he had wandering pains in his legs and feet, with a burning sensation. They also felt as if swollen and large. Then followed difficulty in walking, especially in the dark and when his eyes were closed. He has the feeling of a constriction around the thighs and chest, his patellar reflex is gone, there is incontinence of urine, no sexual desire, diarrhœa usually, and the characteristic ataxic gait. He was treated by a noted Boston specialist, but was given only iodide of potassium, with galvanism to his spine and Faradism to the muscles of the leg. Not improving, he placed himself under the care of Dr. Dana, who is using extension. To obtain it, he uses the ordinary tripod and harness which orthopœdists employ in applying plaster jackets. As is well known, this consists of a strap under each arm, and one under the chin and the back of his head. On the latter strap falls most of the weight. By means of pulleys the man is lifted entirely off his feet. The extension at first lasted only thirty seconds, but the time has been slowly increased until now, after three weeks, it lasts five minutes. In the meantime, the patient is getting nitrate of silver and chloride of gold and potassium, with foot-baths, rest in bed and a highly nutritious diet. Already the man is improving. He has less pain, the sensation in his feet has improved, and he holds his urine better. Dr. Dana is also using the extension treatment on a patient in Bellevue Hospital, to which he is a visiting physician.

Writing of locomotor ataxia brings to mind an instructive incident which occurred in Bellevue Hospital last week. One of the visiting physicians was making the ordinary tests for tabes dorsalis, and told the patient to walk with his eyes closed. He tried to do so, but fell so heavily that he broke his arm. This was in the presence of fifteen physicians, but none was near enough to catch the patient.

Dr. Francis Valk, Professor of Diseases of the Eye and Ear at the Post-Graduate School, has succeeded in grafting the cornea of a rabbit upon the eye of a woman, his being, as the writer understands, only the second successful case. The patient was 44 years old, born in Ireland, the mother of three healthy children, and the possessor of an unusually good personal and family history. Three years ago she had a gonorrhœal ophthalmia which left her totally blind, so that she could not distinguish light from darkness, the cause of the blindness being opacity of the cornea. On April 26, Dr. Valk operated on the left eye. With a trephine, specially constructed for the purpose, a piece of cornea as large as the end of a lead pencil was removed from the woman's eye. Then a rabbit was chloroformed and a similar piece removed from its cornea. This was immediately carried over to the woman's eye on a spatula and nicely fitted in. The eye was washed out with boracic acid, the lid lifted into place, a piece of cotton placed on it and a circular head-bandage applied. Nothing else was done. The operation was short and simple and, though the rabbit died under the chloroform before the piece of cornea was removed, the graft lived and united by first intention. There was no fever and at the first dressing, a week later, the union was perfect. The grafted cornea was at first totally opaque, but it is gradually clearing up, until now the woman appreciates

not only light but also color, and a perfectly clear cornea is the anticipated result. The right eye was operated on May 11, with a similarly successful result. The second rabbit, however, was not chloroformed, cocaine being used instead. The trephine used is an ingenious little instrument. It has a sharp cutting edge and works with a spring. It is wound up, and then, when in place, a lever is touched and the spring causes the cylinder to whirl around, the cylinder being gauged to go to a certain depth and no deeper. As the membrane covering the aqueous humor is not ruptured, this fluid is not lost. In one eye this membrane was also opaque, hence the sight can not be regained in that eye. The patient, however, will have one good eye and the doctor has succeeded in demonstrating that the operation can be successfully done. The antiseptic precautions used were surprisingly few. The eye was not washed and the instruments were not placed in any solution. The operator did not even wash his hands. In short, the only antisepsis used was a slight wash with a solution of boracic acid after the graft was in place. The graft, after being taken from the rabbit's eye, was not dipped in an antiseptic solution but was carried immediately to the patient's eye on a spatula, which was previously wiped clean on the operator's coat sleeve. Notwithstanding all this, there was primary union throughout in both operations.

Dr. Valk has also made another step forward in eye surgery, by devising a means of removing a cataract without iridectomy. He makes the ordinary incision in front of the iris and then, by means of a retractor which he has invented, he dilates the pupil so that the opaque lens can be scooped out. This leaves the iris intact. It is a neat operation and will doubtless be popular.

For chronic indolent ulcers, Dr. S. J. White, Jr., House Surgeon of Bellevue Hospital, uses a paste of balsam of Peru and iodoform, over which is placed an antiseptic dressing of bichloride of mercury gauze. It works admirably, and the ulcers close up rapidly. There are no fixed proportions of the ingredients, the iodoform being stirred into the balsam until the desired thickness of paste is obtained.

Dr. V. P. McGibney being detained by the sickness of his son, his clinic on orthopœdic surgery at the New York Polyclinic last week was held by Dr. J. B. Bissell of Bellevue and Forty-second Street Hospitals. The subject was tubercular ostitis of the ankle, a child with this disease, commonly known as white swelling, being presented. The disease is comparatively rarely found at the ankle. Out of 321 cases treated at the Forty-second Street Hospital last year, the ankle was affected only eleven times. Most frequently it is found at the hip, then in the knee, shoulder, and lastly in the ankle. Its symptoms are: swelling—uniform and not localized; stiffness—little, perhaps no, motion; atrophy of the muscles—the patient's leg showed a marked diminution in size; flabby muscles; heat; lameness and pain not proportioned to the amount of disease, as extensive disease may not be accompanied by much lameness or pain, or the contrary. Lastly is the cry of ostitis, chiefly heard at night. The lameness is characteristic and once seen is always a valuable sign. The nature of the disease is acknowledged to be tubercular. The New York Clinical Society last year appointed a committee to investigate the matter. It thoroughly analyzed forty cases, and found an hereditary taint in all. If traumatism occurs it acts only as an exciting cause. Though the treatment may not much vary, the affection is to be differentiated from acute arthritis, acute epiphysitis, bursitis, sprains, contusions, etc. The patient had been ill for a year, and hence all affections except bursitis were excluded. In the latter, the swelling is localized over one point, usually externally and anteriorly, where are located the bursæ of the tibialis anticus, extensor proprius pollicis, extensor longus digitorum and peronei muscles. In acute synovitis, the swelling is across the anterior portion of the joint where the capsule is thinnest. Acute arthritis is marked by an exceedingly rapid progress and great infiltration of pus; abscesses form, the bones are affected, and there are marked pyæmic symptoms. The treatment is very generally conceded to be complete rest. Some use felt or leather splints, but more preferable are plaster-of-Paris splints, with the foot placed at a right angle to the leg so that, if anchylosis does occur, the limb is in the best possible position. In children able to walk, a Thomas splint is used. It is simply two bars of iron surmounted by a ring through which the leg goes, and hence the child walks with all his weight caught on the perineum. The sole of the other shoe is enlarged. Cases last from six months to six years. Some go on quietly, with the patient in good health; but as a rule abscesses develop, sinuses form, there is hectic, etc. The question arises, shall the abscess be opened? It is a mooted question, but the

best men are in agreement that if it is very large and acute, and pyæmic symptoms develop, the abscess should be opened; otherwise that it be let alone. If it is opened, as little bone as possible should be removed, as excision gives bad results, and if too much is removed, no union results and there is a worse than useless joint. The best plan of treatment is the expectant, giving cod-liver oil, iron, good air, etc., and treating symptoms as they arise.

LETTER FROM BERLIN.

(FROM OUR SPECIAL CORRESPONDENT.)

BERLIN, April 27, 1889.

The Eighteenth Congress of Surgery.—Esmarch on Carcinoma.—Horsley on Injuries of the Cortical motor Region.—Heidenhain on the Causes of Relapse in Cancer.—Schuchardt on Ozæna.—Bramann on Symmetrical Gangrene.—Schinzinger on the Prevention of Relapse of Mammary Cancer.—Thiersch on Extraction of Nerves.—Angerer on Diagnosis of and Operation for Stenosis of the Pylorus.—Schmidt on Extirpation of the Larynx.—Oppenheim on Traumatic Neurosis.—Lauenstein on Complete Extirpation of the Knee joint.—Gerstein on artificial Closure of Cranial Defects.—Mikulicz on the Operative Treatment of Perforating Peritonitis.—Leser on Actinomycosis.—Hanau on Inoculation of Carcinoma.—Mosler on Myxœdema.—Hoffa on newly discovered Ptomaïnes.—Ritasato on pure Cultures of the Tetanus Microbes.—Credé on Surgery of the Gall-bladder.—Waitz on Congenital Elephantiasis.

The Eighteenth Annual Congress of Surgery was opened in the great hall of the University by an address by Prof. Bergmann, in which he bade the numerous and distinguished guests welcome. After a brief reference to the case of Emperor Frederick, he called for three cheers for Emperor William II, the protector of art and science. Among the notable foreign guests were Horsley, of London and Billroth, of Vienna, whose sixtieth birthday just happened to be on the opening day of the Congress. The following are the essential features of the most interesting papers read:

In speaking of carcinoma, Prof. Esmarch said: "Every surgeon is familiar with a type of ulcerating neoplasms, occurring on any portion of the body but preferably on the tongue and lips, which in appearance and course are sometimes scarcely distinguishable from cancer. The differential diagnosis in such cases is, however, of great importance, as these pseudo-cancers often yield to medicinal treatment and trifling operations, while true cancers call for an early and thorough removal by the knife. In all doubtful cases a careful microscopical examination is an absolute necessity, even if, to obtain a particle of the tumor for examination, repeated and deep incisions are required. The greatest resemblance to cancer is presented by the syphilomata, especially if they appear many years after the infection or late in life as the result of hereditary transmission. Often the diagnosis is to be made by exclusion; and syphiloma can be diagnosticated if, after microscopical examination, cancer, tuberculosis, and actinomycosis have been excluded. A syphiloma readily assumes a malignant nature if not extirpated in time. The question as to the origin of malignant tumors is of vital interest, though, unfortunately, it is not yet definitely settled. An irritation, especially a continued one, appears to be the principal etiological factor, taken in connection with a certain predisposition—mostly inherited—and a lowered power of resistance. Besides, it is unquestioned that papillomata, atheromata, syphilomata, and condylomata *can assume a malignant character.* All other theories of the pathogenesis of cancer—such as Scheurlen's (microbic origin) or Cohnheim's (from embryonic cells), or those advanced by Thiersch and Waldeyer—are no longer tenable. The formation of sarcomata on a syphilitic base gives us a general idea of the origin of malignant neoplasms. A syphilitic affection apparently extinct leaves behind it a tendency toward proliferation of the connective tissue which, if removed by the knife, returns obstinately and, like the most malignant cancer, may lead to a general metastasis. The hereditary predisposition to syphiloma may have been transmitted from remote ancestors, several intervening generations being exempt."

In speaking of the recognition of injuries of the cortical motor region, Mr. Victor Horsley said that his researches proved a connection between certain points of the motor centre of the brain and various extremities. Thus, he had determined the central points presiding over the motility of the single fingers, the wrist-joint, the arm,

the hip-joint, the knee-joint, and the toes. *Vice versâ* he was enabled to judge of the condition of those central points by the phenomena presented by the corresponding extremities. He has succeeded in this way in ascertaining and localizing various injuries of the motor region.

Heidenhain said that relapses in cases of cancer are invariably caused by cancerous portions left behind, and as his observations have shown this is especially the case after operations for cancer of the breast. It is, consequently, important to remove not only the cancerous portion of the breast, but also the pectoral fascia and a part or the whole of the pectoral muscle, according to the extent of its implication. This operation, which in addition has the advantage of removing the ordinarily suspected Mohrenheim's cavity, is not a bloodier one than the usual operation, and does not induce greater functional disturbances. It is very desirable to trace the migration of the cancer cells in order to get the proper limits for the operation.

Schuchardt remarked that the investigations on ozæna of Volkmann and himself have revealed, as the cause of ozæna, a transformation of the nasal ciliary epithelium into pavement epithelium, accompanied by putrid decomposition.

Bramann presented three boys, brothers, ranging in age from seven to thirteen years, suffering from gangrenous lesions on the fingers and toes. A close inspection demonstrate the symmetrical nature of the lesions. As there is not the slightest traceable cause for the affection, a nervous predisposition or, possibly, disease of the spinal cord must be regarded as an etiological factor. In the discussion on the subject several similar cases, for the most part of a traumatic character, were reported.

Schinzinger, in speaking of the prevention of relapse of mammary cancer, made a bold and original proposal. To prevent the return of cancer of the breast he advocated, if the woman had not yet reached her change of life, the removal of the ovaries. Cancer of the breast is the more malignant the younger the patient is, and the removal of the ovaries, the author said, would cause the woman rapidly and prematurely to grow old and the breasts to wither. The results of Schinzinger's heroic treatment will be looked for with great interest.

Thiersch said that many cases of neuralgia have been successfully treated by extraction of nerves. The great obstacle in this operation is the difficulty of getting well up near the origin of the nerve, which is of course very desirable. To facilitate this aim Thiersch has constructed a number of forceps which have proven very valuable, especially in extraction of branches of the trifacial nerve. In this connection he referred to a smith living near Leipzig, who enjoyed quite a reputation for instantly removing even the most violent toothache by a puncture of the face. He evidently punctured the auriculo-temporal nerve. Such an operation, however, is to be condemned, as the destruction of so important a nerve causes serious injury to the muscles supplied by it. There is, besides, considerable danger of injuring the facial nerve, which runs near the auriculo-temporal nerve.

Angerer said the diagnosis of pyloric stenosis is made by inflating the stomach with carbonic acid gas—generated by the administration of bicarbonate of sodium and tartaric acid—or by pumping air into the stomach. These measures serve to show whether the suspected swelling is in the stomach or in some neighboring organ. In the former case, resection affords fair prospects of success, and in the latter instance, a gastro-intestinal fistula will at least bring alleviation. The results of such operations are the better the sooner they are performed. As an anæsthetic for these operations, Thiersch recommended Rocher's plan, viz., giving chloroform in the beginning and ether later. Lauenstein called attention to the diuresis produced by the preparatory washing out of the stomach, one patient voiding fifty-five ounces of urine on the day following the washing out of the stomach. The cause of this diuresis appears to be the sucking up of the water by the tissues, though physiologists have doubted this capacity when there is so serious an affection of the stomach.

Schmidt presented a patient from whom about two years ago the entire larynx had been removed on account of cancer. The patient enjoyed good health, and his speech was all that could be desired; he had no artificial larynx and breathed through a canula.

Oppenheim's paper on traumatic neurosis created universal interest, all the more as it was illustrated by five patients suffering with the affection. The first patient was thrown and fell upon his left shoulder; the second was bruised by a car; the third was caught by an engine and injured in the back; the fourth fell from a locomotive; and the fifth was injured on the head by a falling wall. The nervous phenomena pre-

senting themselves after disappearance of the immediate consequences of the injuries—such as swelling, etc.—consisted in various nervous disturbances, such as paralysis, anæsthesia, loss of mental activity, and difficulties of speaking and hearing. In the first and second patients the lesions remained limited to the injured half of the body; the third patient presented a singular and sad appearance; all the muscles of the trunk were in a state of violent and permanent convulsion. The pulse ranged in all the cases from 100 to 140, and great mental depression and insomnia were also universally present. Formerly such affections were frequently interpreted as simulations, as the existence of such nervous phenomena was regarded as impossible without a palpable spinal lesion. The present light of neurological science has dispersed this erroneous view.

Lauenstein's paper on complete exsection of the knee-joint gave rise to an interesting discussion regarding the significance of the ligamenta cruciata, the preservation of which he regarded as essential to functional integrity of the joint. König, on the other hand, said these ligaments served merely as an inhibitory apparatus for rotation, and could be cut without any scruples, all the more as they were sure to reunite again.

Gerstein described his method of reinserting portions of the skull which, by some traumatic cause, have been blown off. If strict antiseptic precautions are taken, bony reunion will result in the majority of cases. Horsley emphasized the importance of immediate replacement.

Mikulicz dwelt especially on the difference between the acute, diffuse, septic form of peritonitis and the progressive purulent, fibrinous, perforating form. In the former, laparotomy is a useless measure, while in the latter this operation is a necessity. The operator has to find out the several foci of suppuration and to empty them; but has to be careful not to disturb the natural connection of the intestinal loops which form a very desirable obstacle to the extension of suppuration. Antisepsis is of little importance here, a mechanical elimination of the pus being solely required. Nor is it necessary to hunt anxiously for the perforation, which heals spontaneously in a short time. To prevent the coming forward of intestines on coughing and vomiting, loose sutures are to be inserted, and a careful after-treatment (diet, opium, etc.) is to be instituted.

Leser said that actinomycosis, which has been hitherto believed to exist only in the cavities of the mouth, throat and abdomen, has by him been observed also in the skin in three cases. The affection is a rather frequent one in the vicinity of Graz, Austria, where it attacks especially mowers who have injured their fingers. Rotter also denies the rare occurrence of actinomycosis of the skin, as he has himself observed six cases.

Hanau stated that nearly all attempts to produce carcinoma artificially in animals through inoculation with carcinomatous matter, have hitherto proved futile. He, however, has succeeded in this inoculation in dogs and rabbits, and in a single instance in a man, whose case was an absolutely hopeless one.

Mossler presented a case of myxœdema of unusual interest. The patient, a lady in the prime of life, was suddenly attacked by the disease without any apparent cause. The affection was ushered in with a swelling of the skin beginning on the thumb of the left hand, and soon spread over the entire body, causing a dreadful disfiguration of the once handsome woman. The expression of the face is dull and stupid, and the swollen eyelids render the eyes exceedingly small in appearance. Speech and hearing are perceptibly defective as the result of the extensive swelling of the mucous membranes. The use of her limbs is likewise greatly impeded. Both the etiology and the therapeutics of the disease are absolutely blanks as yet. As usual, nervous conditions are said to be the causative agencies. Some observers have pointed to the thyroid gland as the possible cause of the disease, as this organ is usually found greatly diminished in size in this and in similar affections. In the patient presented, the thyroid gland is so small that it can scarcely be felt, and the entire affection recalls strikingly the phenomena of cachexia strumipriva, which is observed after total extirpation of goitre. Horsley, who has studied this disease in particular, presented various sections taken from patients with myxœdema, and also called attention to the peculiar contraction of the pupil always observed in this affection.

Hoffa said that the researches of numerous bacteriologists have established the doctrine that all intoxications of the septicæmic type are caused by certain ptomaines, which are regarded as the products of tissue changes or of secretions of specific microörganisms in the blood. Hitherto the exact nature and the chemical composition of these ptomaines have eluded all investigation. The author claims the credit of having first ascertained the exact chemical con-

stituents of this poison. Experimenting on rabbits which had died of septicæmia, he succeeded in isolating the pathogenic ptomaine and in ascertaining its chemical nature. The composition of the ptomaine of septicæmia is that of methylic guanidin, and is represented by the formula of $C_2 H_7 N_3$. This chemical, injected into the lymphatic glands of healthy rabbits, causes the exact phenomena of septicæmia, which the author proved before the Congress. Hoffa has also discovered the specific ptomaine of anthrax, the formula of which he found to be $C_2 H_6 N_2$.

Ritasato, who was mentioned in the last Berlin letter as the discoverer of the musk bacillus, is the first bacteriologist who has succeeded in preparing a pure culture of the specific microbe of tetanus. It is a bristle-bacillus, which occurs in the superficial strata of the earth, and, when injected into animals, causes tetanus. Rosenbach has detected this bacillus also in the oral secretions of men affected with tetanus. Ritasato's method of obtaining a pure culture of the bristle-bacillus is as follows: The mixture containing this bacillus, in conjunction with other microörganisms, was placed in an incubating stove at a temperature of 97°-100.2° F., where a prolific multiplication could take place. He found that at a temperature of 176° F.—provided it was not kept up too long—all germ life perished with the exception of the spores of the bristle-bacillus, which could thus be obtained in a pure culture. Ritasato presented a pure culture and tried its action on mice, with the anticipated result, before the Congress. The tetanus bacillus is able to resist both heat and chemical agents to a considerable degree; it perishes when exposed to steam at the temperature of 212° F. in five minutes, and in five hours if exposed to the action of a five per cent. solution of carbolic acid. Its toxic effects are not attenuated through inoculation, but are destroyed by the action of dilute muriatic acid.

Credé, in speaking of the surgery of the gall-bladder, said that dogs in which the gall-bladder has been removed show great voracity for some time, but soon decrease in weight; later their weight increases again. Credé has observed the very same condition in two patients in whom he had removed the gall-bladder. The explanation is, that at first the fatty matters cannot well be digested in the intestines, owing to the absence of a sufficient quantity of bile, which after removal of the gall-bladder enters the intestines constantly in a small quantity instead of the physiological plentiful supply at the needed time. Nature, however, forms—as the autopsy of animals and men has shown—an artificial reservoir in the common bile duct, and thus re-establishes the lost physiological conditions, which result in the subsequent increase of weight.

Waitz presented a child with congenital elephantiasis. The legs of the otherwise well-formed child, which was one year and a half old, showed an enormous hypertrophy both in length and thickness, especially marked in the left leg. The clinical history was very unsatisfactory. The mother knew of no possible cause except a great excitement experienced by her during a visit to a circus, shortly before her confinement.

In conclusion, I may mention that a magnificent exhibition of surgical instruments and of bacteriological specimens was prepared in connection with this Congress, which, as all agree, was a perfect success.

PERISCOPE.

Treatment of Aneurisms of the Aorta.

In a communication to the Berlin Medical Society, April 3, Dr. Litten said that there were some aneurisms of the aorta with which the patients can live from ten to twenty years; but the average duration of life is from fifteen to eighteen months. Death may arise from marasmus, from compression of the trachea or of a bronchus, through an intercurrent disease, or even by rupture of the aneurism into the pleura, pericardium, trachea or bronchus. Danger to life resides chiefly in the tendency of aneurisms to increase progressively in volume.

Treatment is essentially symptomatic. Hypodermic injections of antipyrin are excellent for the pain. For the insomnia, sulphonal should be tried before having recourse to morphine. In England and France iodide of potash is considered a specific for aneurism. This opinion is the result of the belief in the syphilitic origin of the great majority of aneurisms; however that may be, the iodide acts favorably, especially when used along with digitalis. In the paralyses of the recurrent laryngeal nerve electricity renders real service. Although the vocal cord that is paralyzed does not recover its mobility, yet the other one is benefited by the electricity. In the

case of perforation of bony walls—as of the sternum, etc.—it will be necessary to protect the aneurism by means of appropriate bandages. Radical treatment of aneurisms, by galvano-puncture, by injection of coagulating liquids, or by the introduction of foreign bodies, etc., always fails and often even accelerates death.

Dr. Senator said that he could not accept Dr. Litten's opinion, which he called nihilistic. In aneurisms of the abdominal aorta, he says he has often succeeded in arresting the affection by putting the patient on his back for several months, by methodical compression, and by the use of iodide of potassium. Of eight cases of this kind three have been, so to speak, cured. Prognosis is naturally much worse for aneurisms of the thoracic aorta. Iodide of potash may be considered as a curative remedy.

Dr. B. Fraenkel declared that in his experience electricity was of no service whatever in paralysis of the recurrent laryngeal nerve in aneurism.

Dr. Ewald said his own experience was analogous to that of Dr. Senator. In addition, he stated that even in persons who present no visible manifestation of syphilis, an autopsy frequently establishes the syphilitic aspect, and atrophy of the base of the tongue, which is characteristic of syphilis.—*Bulletin Médical,* April 10, 1889.

Eczema of the Nails.

Dr. de la Harpe, *privat-docent* in the University of Geneva, mentions in the *Revue Médicale de la Suisse Romande* a somewhat rare case of eczema of the nails which came under his notice while he was acting as medical officer at the well-known baths of Louèche, or Leuk. The patient was a man of sixty, who had been sent to Louèche by Professor Hardy. There was no history of gout or other hereditary disease, and up to two years previously the nails had been in excellent condition. The first sign of anything wrong that was noticed was a slight redness about the ungual furrow of the ring finger of the right hand, which was at first supposed to be panaris, but instead of going on to suppuration it was followed by morbid changes in the nail itself, which soon became thickened and friable, with a roughened surface. The nails of the other fingers on both hands subsequently became affected, as shown in figures appended to the paper. When seen by Dr. de la Harpe, the affected nails were swollen, bent transversely, and marked with longitudinal striæ or grooves. Two apparently healthy nails showed fine depressed points. Regarding the cause of these appearances, which are the first signs of the commencement of the affection in otherwise normal nails, Dr. de la Harpe remarks that he has seen a case of chronic eczema of the hand in which there were a number of longitudinal grooves on the nails, some of them interrupted—that is to say, in sections. The punctate marks on the nails in the case in question may possibly be analogous to the interruptions noticed in this latter case. As to the treatment by means of the Louèche waters, it appears to have effected marked improvement.—*Lancet,* March 23, 1889.

New Cocaines by Synthesis.

The endless activity of synthetical chemistry has lately been markedly demonstrated in connection with cocaine. It is not so long since cocaine became of such great surgical importance, in spite of the difficulty of separating it from the leaves, and already it has been prepared artificially from benzoylecgonine by introducing the methyl group into it. Recently Einhorn has announced and described three further substitution compounds in which the place of methyl is taken by other groups. One of these is the lower homologue of true cocaine, while the others are metameric or higher homologues. Two of these could not be obtained in a crystalline form, but only in the form of oil. The third, however, and the salts of all three, are crystallizable. So far, it has not been stated whether any of these new "cocaines" possess any special therapeutic properties. Judging from experience with other artificial drugs, it seems probable that they may in course of time be substituted for the true vegetable alkaloid, but that, until they can be prepared absolutely free from impurities, we shall be likely to hear further of untoward results from the use of cocaine. On the other hand, the importance of this discovery can scarcely be over-estimated if it can be worked with sufficient precision to provide for an increased supply of cocaine of certain composition and good quality. Any increase in the quantity of cocaine in the market will reduce the price and favor its more extensive employment. It remains to be seen whether the new cocaines possess similar therapeutic properties, and whether they can be prepared artificially more economically than the natural alkaloid, or will exist only as chemical curiosities.—*Lancet,* April 6, 1889.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Physician's Daily Pocket Record, - - 1.00
Reporter and Pocket Record, - - - - 6.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE DISASTER AT JOHNSTOWN, PA.

In the accounts of the terrible disaster which suddenly overwhelmed the town of Johnstown, in Pennsylvania, on Friday, May 31, it is not surprising to read of the heroism of the physicians of the ill-fated valley of the Conemaugh; nor is it surprising to find that, as soon as the news reached their professional brethren in all parts of the State, they hastened to the assistance of those involved in ruin or distress. This is just what the common life of physicians prepares them for; and such a response is precisely what would be expected. None the less is it gratifying and inspiriting to find the action of the physicians of Pennsylvania so quick and so spontaneous. Their willingness to run to the help of the distressed contributes to illuminate a cloud of disaster which, even with this relief, is appalling to contemplate.

The present needs of the sufferers is—it is to be feared—but a portion of the whole; and the physicians of this State may be—and probably will be, called upon for further aid. Men may be needed to go to the help of those who are on the spot, in caring for the sick and injured, and in warding off the effects of the pestilence which may follow the flood and fire. No doubt, also, money will be needed there, and the benevolence of our fellow citizens may be insufficient for the needs of our professional brethren. If this shall prove to be the case, we must be ready to add to what has been done already, and to fill up the measure of our fraternal aid to those whose misfortunes we have been spared.

At this writing there is no indication as to the best channel in which to direct even the best intentions; but this will come soon, and then the REPORTER will be happy to be the medium of communication between the members of the profession as to what shall be done in the emergency which has arisen.

PROGNOSIS OF HEART DISEASE.

The invention and improvement of the stethoscope and of the sphygmograph have led to a closer study of diseases of the heart, as the result of which our ability to recognize them early has been materially increased. In more recent years, also, the treatment of heart diseases has improved, especially by the judicious use of Oertel's method, a good description of which was published in the REPORTER, May 26, 1888. These two factors—greater power in diagnosis and improved methods of treatment—have naturally tended to make the prognosis of affections of the heart more hopeful.

Prof. Leyden recently drew attention to this circumstance in a communication published in the *Deutsche med. Wochenschrift*,

April 11, 1889. This distinguished clinician says that sudden death is liable to occur in aortic insufficiency, both in grave cases associated with considerable dilatation and hypertrophy, and also in cases in which the lesion is slighter and better compensated. He admits that it may also occur in true angina pectoris—that is to say, in the form which is dependent upon sclerosis of the coronary arteries; but he declares that in all other varieties of heart disease sudden death is a relatively rare occurrence. In mitral affections, for example, it occurs in only about two per cent. of the cases, and is therefore so rare that the physician may neglect it in prognosis. In fatty degeneration of the heart sudden death occasionally occurs, it is true, as it does in the later stages of acute diseases and in the beginning of convalescence from them. It may also occur under the influence of overexertion or strong emotions; but, as Leyden points out, these are rather general conditions which lead to heart weakness than affections of the heart themselves. And, after all, they result in sudden death so rarely that they need not be reckoned in prognosis.

In addition to the information gained by an examination of the heart and the condition of the circulation, it should be borne in mind, in making a prognosis, that the age, sex and circumstances of the patient, as well as the apparent effect of treatment, have each to be considered in estimating the probable result of the disease. For instance, little children do not bear heart affections well, while older children and young persons, on the contrary, do bear them well. In the aged the prognosis is grave, because heart affections are, at this period, very commonly the consequence of arterio-sclerosis—a disease which progresses steadily and is never arrested.

As regards sex, the prognosis of heart disease in general may be said to be more favorable in women than in men, as would naturally be supposed from the fact that women are less exposed to the influences which determine arterio-sclerosis and grave cardiac affections, namely, physical overwork, venereal excesses, and alcoholism. Moreover, aortic insufficiency—the most unfavorable form of heart disease—predominates in men, whereas women are more subject to mitral stenosis. The latter lesion, Leyden states, is relatively benign; but he should have made an exception in the cases in which pregnancy complicates it, for then it is very fatal.

The patient's manner of life and his ability to take proper care of himself are important elements in the prognosis of heart disease; and it is for this reason that better results are obtained in the treatment of heart disease in private than in hospital practice. Furthermore, the readiness with which the heart is found to respond to cardiac tonics and stimulants is of importance. If such remedies fail, the outlook is of course more gloomy, as a lack of recuperative power on the part of the heart is indicated. Digitalis is the best remedy for use in judging of the power of the heart to respond to stimulation. But failure with it does not leave us entirely powerless, in spite of the fact that the effect of analogous remedies and methods of treatment is more uncertain.

Medical men, and the more intelligent of laymen, have long known that the existence of heart disease, in which compensation is good, is compatible with long life and comparative comfort, if the patient's circumstances permit him to live on a comparatively even plane of life, and with the best treatment of his heart trouble. They have also known that, when death results from heart disease, it is the exception, and not the rule, for it to come suddenly. Nevertheless, the average layman still regards the diagnosis of heart disease as equivalent to a sentence of death at no very distant period, and is continually in dread of sudden death.

This false conception will continue to influence the public mind until general

practitioners, and especially family physicians, succeed in establishing a correct view of the matter in the minds of their patients.

It is to be hoped, therefore, that the views which we have just cited may be carefully considered in order that as hopeful a conception as is proper may be formed of the prognosis of heart disease in general.

WOMEN TEACHERS OF PHYSIOLOGY TO GIRLS.

It is reported that the principal of a school in a New Jersey village has recently been charged with using the opportunity afforded him when teaching physiology to the school girls to make remarks which they thought to be immoral. The charge has been denied, and on investigation it has fallen to the ground. The teacher, however, has expressed the opinion that its mere discussion would probably compel him to give up his position and to leave the village.

This is an unfortunate outcome of what was doubtless meant to be an instructive exercise, and it illustrates the dangers that beset men who discuss before young women topics which are not usually broached under these circumstances. The study of physiology by girls cannot well be directed by a man, unless it is kept within restricted limits. There are matters connected with physiology which no man can discuss with girls without impropriety, but which it would be well for them to know about. For this reason it would be better if physiology should be taught them by a woman. There are now so many intelligent women physicians in this country that few places of any consequence are without them, and it ought not to be hard to find enough to teach all the physiology that is needed in the education of girls.

This work offers a field of usefulness to women physicians which is of great importance, and if it were occupied rightly by them the result could not fail to be of advantage to girls, many of whom grow up ignorant of physiological facts, a knowledge of which might save them from much unhappiness and some misfortunes.

THE PENNSYLVANIA STATE SOCIETY.

The members of the Pennsylvania State Society present at Pittsburgh have adjourned to September 3 the meeting which was to have been held in that city during the current week, in view of the fact that the disaster at Johnstown, and the floods which visited almost the whole of the State at the same time, have so disorganized the railroad service, that it has been impossible for the members of the Society, in any numbers, to attend the meeting.

The arrangements of the REPORTER have been interfered with by this postponement; for we had prepared to publish a number of the most valuable papers of the Society immediately after its adjournment. Regard for the rights of the Society and the wishes of the authors has, however, necessitated our withholding them from the press until the matter can be adjusted satisfactorily to all concerned. These circumstances have led to a delay in the appearance of this issue of the REPORTER which our readers will understand.

NEW HAMPSHIRE STATE MEDICAL SOCIETY.—The Ninety-eighth Annual Meeting of the New Hampshire State Medical Society will be held in Concord, Monday and Tuesday, June 17 and 18, 1889. All applications for membership in the Society must be made to the Secretary, Dr. Granville P. Conn, of Concord, before the meeting of the Councillors, on Monday evening, June 17. The programme issued by the Committee of Arrangements promises to be interesting; it contains, in addition to other useful information, a list of the stations at which it will be necessary to purchase tickets in order to obtain them at reduced rates.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

A COMPENDIUM OF DENTISTRY FOR THE USE OF STUDENTS AND PRACTITIONERS. By Jul. Pareidt, Dental Surgeon to the Surgical Polyclinic at the Institute of the University of Leipsig, etc. Authorized translation, by Louis Ottofy, D.D.S., Lecturer on Physiology, Chicago College of Dental Surgery, with notes and additions by G. V. Black, M.D., D.D.S., Professor of Pathology, Chicago College of Dental Surgery, with numerous illustrations. Large 8vo, pp. xii, 229. Chicago: W. T. Keener, 1889. Price, $2.50.

This book contains an able discussion of the disease processes which attack the teeth, the maxillary bones and the mucous membrane of the mouth, as well as of the anomalies to which the teeth are liable. This, and the treatment of these conditions is considered in a most thorough and scholarly manner, as might be expected of the competent hands through which the work has passed. The part of the book devoted to mechanical dentistry is brief, but good. In the preface, the author calls attention to the importance of a knowledge of the diseases of the teeth to the general practitioner, and recommends a study of this subject to those who usually do not care to give it much attention. In this we think he is quite right, and can second his recommendation with the firm conviction that at least an elementary knowledge of the principles of dentistry would be of the greatest service to most physicians.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

267. Should the State Take Care of its Inebriates? By E. J. Kempf, M.D., Jasper, Indiana. 24 pages. Price, 10 cents.

268. Graves' Disease. By William C. Bailey, M.D., Albion, N. Y. From the *Buffalo Med. and Surg. Journal*, August, 1886. 21 pages.

269. The Electrolytic Decomposition of Organic Tissues. By George H. Rohé, M.D., Baltimore, Md. From the *New York Med. Journal*, December 1, 1888. 15 pages.

270. Poisoning by Chrome Yellow used as a Cake Dye. By David Denison Stewart, M.D., Philadelphia. From the *Medical News*, January 26, 1889. 24 pages.

271. Angina and Pneumonia before 1857 and Since, with the Pathology of Diphtheria in its Various Phases. By William Henry Thayer, M.D., Brooklyn, N. Y. From the *New York Medical Journal*, January 26, 1889. 22 pages.

272. A Defence of Electrolysis in Urethral Strictures, with Documentary Evidence. By Robert Newman, M.D., New York. From the *Medical Register*, January 5, 1889. 20 pages.

273. The Immediate Application of the Forceps to the After-Coming Head in Cases of Version with Partial Dilatation of the Cervix. By H. C. Coe, M.D., New York. From the *Medical Record*, January 19, 1889. 7 pages.

274. Dreams, Sleep, Consciousness. A Psychological Study. By George M. Gould, M.D., Philadelphia. From *The Open Court*, January 24 and 31, 1889. 24 pages.

275. Report of the Committee on Ophthalmology and Otology. By Seth M. Bishop, M.D., Chicago. From the *Transactions of the Illinois State Med. Soc.*, May 17, 1888. 11 pages.

276. On Corpulence, especially its Treatment by a Pure Milk Diet. By George H. Rohé, M.D., Baltimore. From the *Maryland Med. Journal*, Feb. 9, 1889. 4 pages.

277. On the Microscopical Examination of Urinary Sediment. By William B. Canfield, M.D., Baltimore. From the *Transactions of the Medico-Chirurgical Faculty of Maryland*, 1888. 4 pages.

278. The Gonococcus. By William B. Canfield, M.D., Baltimore. From *The Microscope*, July, 1888. 3 pages.

279. Report on a Case of Pregnancy in the Right Horn of a Uterus Bicornis, etc. By B. F. Baer, M.D., Philadelphia. From the *Transactions of the Amer. Gynecological Society*, 1888. 16 pages.

267. Dr. Kempf opens his pamphlet with the statement that he is not presenting a temperance tract, but a more interesting temperance tract, or a more entertaining arraignment of the system of licensing the liquor traffic we have never seen. The keynote of the argument is found in the sentence: "The State considers 'becoming a drunkard' a personal right, and 'being a drunkard' a crime. Science holds 'becoming a drunkard' to be a sin, and 'being a drunkard' a disease." The question in the title he answers in the affirmative, asserting that the State should erect and maintain homes for inebriates, using for this purpose the money collected for licenses to sell alcoholic beverages, and the fines levied upon those who break the law in consequence of drinking.

As a whole this pamphlet is calculated to do a great deal of good, and as its style is exceedingly interesting, none of our readers will regret it if they follow our recommendation and apply to the author for a copy of it.

268. Dr. Bailey's paper contains an instructive study of Graves' Disease, to which he was led by the experience gained in treating successfully a case of this disorder. The history of his own case is very well described, and the whole subject is gone over in a way which makes his pamphlet a valuable contribution to its literature.

269. After a preliminary discussion of the general principles of electrolysis, Dr. Rohé considers its applicability to the decomposition of morbid organic tissues, and warmly advocates its employment. Without going much into detail, he defends its use in the treatment of fibroids and strictures of the urethra. In regard to both of these he speaks with scorn of those who reject electrolysis, and intimates that a fair trial would convince them of its utility.

270. In this pamphlet Dr. Stewart follows up the history of a number of cases of poisoning with chrome yellow, used by bakers as a coloring agent in cakes, which came under his observation in 1887. He has studied these cases with praiseworthy industry and persistence, and the results of his study are both interesting and instructive. His work furnishes a needed lesson in regard to the danger which may follow the use of artificial dyes in articles of food,

and deserves the attention of all hygienists and toxiologists.

271. Contrary to the opinion of many recent writers, Dr. Thayer holds that diphtheria is essentially a constitutional disease "often with little manifestation in the fauces, and sometimes an entire absence there of the exudation-membrane from which its name is derived." His pamphlet is so full of interesting matter that it would be impossible to summarize it in our limited space, but it will abundantly repay perusal.

272. This is another controversial paper by Dr. Newman, in which he defends his method of treating strictures against the attack of Dr. F. Tilden Brown. Like all of his recent papers this one of Dr. Newman is interesting, and will arouse sympathy. As we have said before, he maintains a struggle against the prevalent opinion of genito-urinary surgeons. But it is evident from this and other of his writings that there is a considerable number of men who share his views and approve of his method. The principle of hearing both sides is peculiarly appropriate to this case, and it is to be regretted that the argument has developed so much acerbity.

273. Dr. Coe makes a warm argument for the immediate use of the forceps to deliver the head after version by the feet, and supports it by reference to a number of cases in which delay proved fatal to the child. He defends the procedure as easy of execution, and as involving no risk except that of lacerating the cervix, which he thinks is not to be compared with the risk of life to the child in case delivery of the head is delayed.

274. This pamphlet is what might be expected from its title. It is a study of the phenomena of dreaming and sleep and consciousness, with a section on "Character, the Soul, and Consciousness." It is vague and unsatisfying, and leads to nothing in particular. It is interesting and furnishes food for reflection, but is too much founded upon the writer's personal experience to admit of general application to the subject discussed.

275. In this paper Dr. Bishop is principally occupied with a description of three instruments of his invention: a pneumatic otoscope, an improved tonsillotome and a nasal speculum. The instruments are ingenious in principle, and calculated to be useful in practice.

276. The title of Dr. Rohé's paper indicates its contents. He discusses the physiological phenomena of corpulence and advocates treating the condition by means of an exclusive diet of skimmed milk, citing two observations which strengthen his conviction of its value.

277. This is a most instructive pamphlet, and every medical man who attempts to examine the sediment of urine microscopically would do well to learn and to follow Dr. Canfield's admirable and practical suggestions.

278. After a short review of the literature of the gonococcus, Dr. Canfield describes the method of searching for it in suspected pus.

279. Dr. Baer reports an exceedingly interesting case of a woman who missed her labor, and came under his care with a diagnosis of extra uterine pregnancy a year afterward. He operated, removed the dead fetus by a modified Cæsarean section, but had to leave the cyst-wall behind. The patient made a good recovery. The case is well described, and interesting remarks are added on the subject of pregnancy in a bicornate uterus in general.

CORRESPONDENCE.

Effects of Sulphonal.

TO THE EDITOR.

Sir: The much talked of sulfonal has lately revealed to me some weak points and ugly traits. For instance—

(1) Mr. G., aged forty-nine, married, has periodical attacks of dipsomania, about once a month, after which he cannot sleep. For several years morphia and bromide of potassium would quiet him pretty fairly. In December, 1888, I began giving him from twenty to thirty, and even forty-five grains of sulfonal, dissolved in hot water, at bed-time or an hour before. The drug invariably keeps him awake and comfortable during the night, and sleep follows, as a rule, sometime the next day. He says it intoxicates him.

(2) W. P., aged thirty-five, married, farmer; had gastro-enteritis during April last. During convalescence he could not sleep day or night. I gave sulfonal, in twenty grain doses an hour before bedtime. He did not "sleep a wink," and was a little delirious.

(3) Miss Mamie W., aged twenty-three, single; is on a visit East from Colorado, where she resides, on account of tendency to consumption. Both parents died of phthisis. After living here from two to four weeks, she always has loss of appetite, rapid and feeble pulse, great debility, a little cough and wonderful sleeplessness, but no fever. This (May) is her fourth visit East in the last four years, and her fourth attack of sickness, with above mentioned symptoms. The evening of the 18th inst. I gave her fifteen grains of sulfonal in very weak hot coffee, at nine P.M., and repeated the dose at half past ten. She scratched all night; was slightly delirious, and did not sleep. The next night I gave her thirty grains, in hot water, at 9 P.M. The same symptoms followed, with nausea and vomiting and marked debility.

Yours truly,

C. H. SHIVERS, M.D.

Haddonfield, N. J.,
May 21, 1889.

—The total number of students at all the Austrian Universities during the winter semester of 1888–1889 was 13,801, 1,388 of which were in the Universities of Lemberg and Czernowitz, which have no medical faculties.

Notes and Comments.

No Yellow Fever in Florida.

Dr. Jerome Cochran, State Health Officer of Alabama, returned May 30 from a trip to South Florida and Havana, made for the purpose of investigating the yellow fever situation. He says that there has been no yellow fever in Florida since January, except one case *reported* in April, at Sanford. In Havana he found little fever, only a dozen to twenty cases a week. The general health of the people is exceptionally good, and Dr. Cochran gives it as his opinion that there will be no fresh outbreak of yellow fever in Florida this summer, unless there is a fresh importation of the disease.

The Disaster at Johnstown.

As our readers have already learned from the daily papers, about five o'clock on the afternoon of May 31 a most disastrous flood, caused by the bursting of an artificial lake, near Johnstown, Pennsylvania, overwhelmed that town and the valley in which it lies. The sympathy of physicians all over the State was at once aroused, and those who could offered their services at once. On receiving a telegram from Dr. Lowman, of Johnstown, asking for medical aid, Dr. William S. Forbes, of Philadelphia, organized a relief party of physicians and promptly started to aid the sufferers, in spite of great difficulties and of the uncertainty of reaching the afflicted city. He took with him as large a stock of provisions, clothing and medical supplies as could be gathered in the short space of time at his disposal.

Other physicians were not idle. At a meeting of the Faculty of Jefferson Medical College it was resolved that an additional relief corps from the staff of the surgical clinic of the hospital should be sent by the earliest train to report to Professor Forbes.

A largely attended meeting of physicians was held at the office of Dr. Harrison Allen, 1933 Chestnut Street, with the view to arrange for the furnishing of medical aid to the sufferers. Dr. John Ashhurst, Jr., presided and Dr. Allen acted as secretary. A committee was appointed to complete arrangements. At a meeting of this committee, held immediately, it was agreed to report to the Mayor and the Citizens' Relief Association, of Philadelphia, and to the Red Cross Society the names of physicians willing at a moment's notice to go to Johnstown in aid of the sufferers. Twenty-five physicians volunteered their services.

The response from Pittsburgh was equally prompt, and accomplished more because access to Johnstown was not cut off from the West, while it was from the East for some days. The details of the work done by medical men from points other than Philadelphia are not as yet fully reported, and due credit can be given to them only in a general way. Further reports will only enhance their credit.

Relations of Scientific Experts to the Administration of the Law.

Willard Bartlett, Justice of the Supreme Court of New York, in a paper read before the Society of Medical Jurisprudence and published in the *Brooklyn Medical Journal*, May, 1889, gives some good advice to physicians called as medical experts in any case. He says:

"Upon the trial, except in the comparatively rare instances in which there is no dispute as to the nature, extent, and consequences of the plaintiff's injuries, the respective parties are assisted by physicians or surgeons, or both, who testify in reference to these matters, and often advise counsel as to the conduct of the medical or surgical part of the case.

"The wise doctor, as it seems to me, will take care not to act in both capacities. If he is to testify in the case, he will not act as assistant counsel; if he acts as assistant counsel, he will keep off the witness stand. There is no good reason why the most distinguished physician should not place his professional knowledge and experience at the service of one of the parties to a litigation which involves questions of medical science. To do so cannot justly subject him to reproach; but it does lessen his fitness and his usefulness as a witness in that litigation. In assisting counsel, he will inevitably come to share the sentiments of counsel as to the result. Just as counsel will seek to bring out every fact that may prove beneficial to the cause of his client, and will endeavor to destroy, as far as may be, the effect of any proof which is injurious to him, so the medical man thus employed will suggest questions for the examination of witnesses on the other side, which will call out answers favorable to the party at whose instance he has been brought into the case. All this goes on before the jury, who fully comprehend where the medical questions really come from. If, afterward, they see

the doctor take the witness stand, it is impossible that they should regard him as otherwise than prejudiced. However truthful his testimony may be, and however correct his opinions, his evidence is the evidence of a partisan, and this fact invariably detracts from its force and effect."

Sulphonal in Night Sweats.

In addition to the hypnotic properties enjoyed by sulphonal, this drug is capable, according to Dr. Böttrich of Hagen, Westphalia, of exercising a most beneficial influence in night sweats. It acts, he thinks, very similarly to atropine, but, unlike it, is quite free from any undesirable effects. He found this property out by accident, having prescribed a quarter of a gramme (nearly four grains) for an old woman of eighty as a sleeping powder. The patient had been suffering from the most profuse night sweats, obliging her to change her things twice during the same night. After the first dose she asked the doctor whether he had not put something into the powder to prevent the sweats. On making further observations, Dr. Böttrich convinced himself that as a rule half a gramme (seven grains and a half) of sulphonal will stop night sweats. Its effects seem fortunately to be somewhat permanent, as even after the drug has been stopped the night sweats are found to be much less severe than they were previously to taking it.—*Lancet*, April 27, 1889.

State Board of Medical Examiners in Tennessee.

The *Southern Practitioner*, May, 1889, contains the full text of the act to regulate the practice of medicine in Tennessee, which was passed very recently by the legislature of that State and signed by the governor. Graduates of medical colleges must appear before the Board of Examiners, present their diplomas, and pass an examination before they can be allowed to practise in Tennessee. The act provides that regular physicians, homœopaths and eclectics, shall be represented on the Board, and that each candidate shall be examined by the representative on the Board of the school to which he belongs. A majority of votes are necessary for a rejection. Quacks are to be fined in any sum not less than $100 nor more than $400 for each offense. Any person practising without the certificate issued by the Board is to be fined $25 for the first offense and $200 for each subsequent offense. The Board is also granted power to revoke licenses for cause.

Death due to Somnambulism.

The *British Med. Journal*, May 11, 1889, states that a Dr. Davidson retired to rest about eleven o'clock one night, and about two hours afterward the attention of the servants was attracted by the noise of some heavy object falling. Dr. Davidson was found lying in his nightdress outside the house, having apparently fallen from his bedroom, which was situated on the third floor. Medical aid was obtained, but he succumbed to the injuries he had received. Dr. Davidson had been for several years subject to attacks of somnambulism, and there can be no doubt that the accident took place while he was in an unconscious condition.

Diagnosis and Treatment of Tubercular Peritonitis.

Dr. Samuel Fenwick, in the course of his lectures on cases of difficult diagnosis, writes as follows upon the diagnosis of tubercular peritonitis in the adult (*Lancet*, March 9, 1889): The diseases with which we are most apt to confound acute tubercular peritonitis are typhoid fever and acute non-tubercular peritonitis, and in some instances the resemblance is so close that it is only by great care and watchfulness that we can avoid falling into error.

As a general rule, tubercular peritonitis of this kind begins suddenly, whilst typhoid is usually preceded by a period in which the patient has been weak, feeble, and feverish. In the former, pain in the abdomen is more marked, and there is tenderness over different parts; whilst pain in the latter is rarely severe, and any tenderness that may be present is confined to the iliac region. In tubercular peritonitis the temperature rises at once, and not regularly, as in enteric fever, and the pulse is usually more rapid. As the case proceeds the temperature varies more in peritonitis, spots are rarely observed, and the stools have not generally the typical appearance of those passed in typhoid; whilst at a later period the persistence or frequent returns of abdominal pain and tenderness and of vomiting, the variations of the temperature, the alternations of constipation with diarrhœa, and the increasing prostration, will in most instances enable you to distinguish between these diseases. In addition to these differences, you will in many cases be able to render your diagnosis more certain by the discovery of fluid in the peritoneum, or by the detection of a tumor in the abdomen; or you may find the signs of effusion in the

pleura or of a consolidation in the apex of one or both lungs.

Still more difficult is it to distinguish between acute tubercular peritonitis and ordinary peritonitis when the former does not assume from the first the typhoid form. In many cases I believe it is impossible to arrive at a certain conclusion in the early stage, for both may attack persons previously healthy, both may be ushered in by similar abdominal symptoms, and it is only by watching the progress of the disease that you can form an accurate opinion. As a general rule, the pain, tenderness, and vomiting are less distressing in the tubercular form, the temperature is lower, and there is more usually diarrhœa than constipation. As the disease progresses, the abdominal symptoms recur from time to time instead of slowly subsiding, the temperature remains high, emaciation becomes more marked, the effusion into the peritoneum is very slowly absorbed, and you may discover signs indicating effusion into the pleuræ or pulmonary consolidation.

As regards the treatment of acute tubercular peritonitis in the adult, he says: In the typhoid form I have usually treated the case as if it were one of enteric fever; that is, the patient has been kept at rest, the food has been restricted to liquids, and cold sponging has been employed whenever the temperature has been unduly high. Quinine in moderate doses in combination with opium has been prescribed to relieve pain and to check diarrhœa. In the cases in which the symptoms were chiefly abdominal the treatment has been directed as in ordinary peritonitis; poultices and hot fomentations have been applied to the abdomen, and small doses of opium have been given to relieve pain and diarrhœa. You must, however, be careful not to induce constipation, for it is usually followed by attacks of vomiting that quickly reduce the strength of the patient.

You may ask whether the washing out of the peritoneum, which is so successful in some cases of suppurative peritonitis, is likely to prove beneficial in this kind of case. I have never seen it tried, chiefly because the real nature of the disease has more frequently been suspected than actually diagnosticated during life; but I do not think it would be of much value, as I have found the fluid serous, not purulent, and the patients have seemed to me to sink from the general acute tuberculosis, and not from the effects of the inflammation of the peritoneum.

Expert Testimony as to Death by Poison.

The Supreme Court of Wisconsin has recently formulated a rule of testimony according to which, when a trial for murder by poisoning is on, any physician whose only knowledge of poisons is that which has come to him from books and college training is not competent to give an opinion relative to the symptoms of the final illness of the deceased with regard to their probable causation by poisoning. This is probably the first time that any court has prescribed such a regulation, but it has so much in its favor that we count upon its gradual extension from court to court as questions arise in regard to poisoning cases. No person may justly be put in jeopardy of his life on the quasi-expert testimony of a witness who has gleaned all that he knows of the subject from the printed page or half-remembered lecture.—*New York Med. Journal*, April 20, 1889.

Ichthyol.

Despite its disagreeable odor, ichthyol has been gradually establishing itself as a remedy of no mean properties. Unna says: "In my opinion we have not up to the present time possessed so effectual a remedy [as ichthyol] for rheumatism." According to Nussbaum—and his opinion is the same as that of Unna, Blittersdorf, and Lorenz—ichthyol is of special service in all diseases associated with hyperæmia and distended capillaries. Though very disagreeable at first to take, the palate and stomach soon become used to it, and it is said to improve the appetite in those cases in which it is indicated internally, as in intestinal, renal, cystic, or urethral catarrh. It is quite compatible with lanolin and other unguent bases, is miscible with mercury, zinc ointment, etc., and dissolves completely in water. A mild ointment (5 per cent.) is pronounced regenerative, a strong one (50 per cent.) resolvent. — *London Medical Recorder*, February, 1889.

Formula for "Lemonade Iron."

The following is the formula for "lemonade iron," a favorite combination with Dr. Goodell:

℞ Strychninæ sulph. . . . . gr. ss
Tinct. Ferri chlor. . . . . f℥iv
Acidi Phosph. dil. . . . . f℥vi
Syr. Limonis . . . . . q. s. ad f℥vi

M. Sig. Dose, two teaspoonfuls three times a day.

Mr. Bishop was Dead.

After all the fuss made over the death of Mr. Bishop, and the assertion that an autopsy had been made on him while he was still alive, the Coroner's jury found the following verdict on May 29: "We, the jury in the case of Washington Irving Bishop, find: First, that he died at the Lambs' Club on May 13, 1889; second, cause of death was coma; third, we further find that while Drs. Irwin, Ferguson and Hance acted in good faith in performing the autopsy upon the body of the deceased, we would state that Dr. Irwin, through overzeal, acted in some haste respecting the direction of the performance of the autopsy." Coroner Levy thereupon discharged the three physicians, who had been held in $2,500 bail each.

Formula for Use in Nervous Anæmic Women.

Dr. Goodell thinks highly of the following combination for use in the case of nervous anæmic women, perhaps with dysmenorrhœa:

Ext. Sumbuli,	
Ferri sulph. exsiccat.	āā gr. i
Asafetidæ	gr. ii
Acidi arseniosi	gr. $\frac{1}{40}$

M. et ft. pil. No. I.

Sig. One pill after meals, to be increased to six pills a day.

Saccharin for Thrush.

Since it has been known that saccharin possesses the property of checking fermentative processes in the intestine it has been frequently employed as an antiseptic. Maurice Fourcier has used saccharin for some time in cases of thrush, and with very good result. In the *Revue gén. de clin. et de Thér.*, No. 11, he speaks of his experience with ten cases, which he treated with applications of a solution of saccharin; in eight cases the thrush disappeared within twenty-four to thirty-six hours, and lasted twice only as long as three days until complete healing occurred. In these cases the applications were badly made. Fourcier employs the following solution:

℞ Saccharin	gr. xv
Alcohol	f ℥ iss

A coffee-spoonful of this solution is added to a half-glass of water, and the affected parts painted with the resulting mixture five times a day. A concentrated solution should not be employed, as it can be injurious. An apothecary who prepared the above solution tasted it by frequently putting his finger, which had been dipped in it, into his mouth. The same evening he was seized with a burning sensation in the mouth and on the day following had an aphthous eruption in the mouth, which however disappeared spontaneously in five days. In the way in which Fourcier employs the remedy it is entirely harmless and very effective.—*Wiener med. Presse*, April 14, 1889.

Proposed Tribute to Dr. Levis.

A Committee, including a number of physicians of Philadelphia, has invited subscriptions for the purpose of endowing a free bed in the Philadelphia Polyclinic, in recognition of the eminent professional services of Dr. Richard J. Levis, who was one of the founders of the Polyclinic, its first Professor of Clinical and Operative Surgery, and from its organization has been President of the Board of Trustees. The sum of five thousand dollars is needed for this purpose, and the Committee which has charge of raising the money requests that subscriptions be sent as soon as possible to the Treasurer, Dr. H. Augustus Wilson, 1611 Spruce Street, Philadelphia.

The Sanitarium at Red Bank.

The Sanitarium Association of Philadelphia, designed to furnish a day's outing to young children, infants and their caretakers, had its thirteenth annual opening at Red Bank, New Jersey, on Thursday, June 6. This excellent institution is the means of giving happiness and health during the summer season to hundreds of infants and young children which otherwise would have little opportunity to obtain much-needed fresh air and recreation. Those contributing to its fund have the right to send children to spend the day at the Sanitarium. Persons affected with any contagious or infectious disease are, of course, excluded.

The Howard Hospital.

The new building of the Howard Hospital, in Philadelphia, which has heretofore been conducted as a Dispensary, was opened May 23. The building will accommodate ten hospital patients besides the necessary rooms for matron, nurses, etc. Accident cases will be admitted at all hours, and clinical instruction will be given by members of the staff. A peculiar feature of the new service will be the sick-diet kitchen, which is intended to benefit invalids unable to get suitable food at their homes.

NEWS.

—Yellow fever is reported to be "very bad" in Vera Cruz, Mexico.

—Dr. G. E. de Schweinitz, of Philadelphia, has removed to 1401 Locust street.

—Prof. H. A. Bardeleben, of Berlin, celebrated his seventieth birthday on March 1.

—Up to Feb. 20 Dr. Waxham had had 188 cases of intubation of the larynx with 60 recoveries, or 31.36 per cent.

—Dr. R. J. Levis, who is summering with the Duke of Sutherland, instead of at Cedarcroft, has lately bought a winter home in Florida.

—A case of leprosy is said to have been discovered at Spring Lake, Wisconsin. The victim is a woman. The character of the disease is well marked.

—Dr. Roswell Park, of Buffalo, has been using powdered sulphate of cinchonidia in surgical dressings. He says it is both better and cheaper than iodoform.

—It is announced that Dr. Robert W. Taylor has been appointed Professor of Diseases of the Skin in the New York Post-graduate Medical School and Hospital.

—Dr. S. P. Moore, who was Surgeon-General of the Confederate States, died suddenly at his residence in Richmond, Va., May 31, of congestion of the lungs.

—The American Society for Psychical Research announces that, unless its income is increased by its members, it will be necessary to close its work by the end of June next.

—Dr. Erasmus M. Pond, a distinguished physician of Vermont, died at Rutland May 31, aged 61 years. He had invented Pond's Sphymograph, and several other important instruments. He was graduated from the Medical Department of Harvard University in 1853.

—Governor Bulkley, of Connecticut, on May 24, vetoed the bill to prevent deception in the manufacture and sale of butter and cheese. This is the bill which was designed to prohibit the coloring of oleomargarine to resemble genuine butter and cheese. The Governor's reasons for the veto are said to be that oleomargarine has been pronounced a wholesome article of food; that the present law sufficiently guards against its sale under false pretenses; and that to prohibit its manufacture entirely would be detrimental to the interests of the people.

HUMOR.

IT WAS A SCOTCH GRAVE-DIGGER who said, "Trade's very dull noo. I have na buried a leevin' cretur for a fortnight."—*San Francisco Alta.*

VERY SHOPPY.—Miss Reeder—"You should read Dr. Weir Mitchell's last story; the scene is laid in the lumber regions." Dr. Schmerz—"Oh, I see; in the small-of-the-back-woods you mean."—*Puck.*

HEALTH JOURNALS insist upon reposing on the right side only, and claim that it is injurious to lie on both sides, but we don't know where they will find a healthier-looking set of men than lawyers.—*Salem (Ore.) Statesman.*

THE CERTAINTY OF THE DOCTORS.—"But, doctor, you said last week that the patient would certainly die, and now he is perfectly well." "Madam, the confirmation of my prognosis is only a question of time."—*Fliegende Blätter.*

A CIGARETTE PREMIUM.—Cigarette smokers will be interested in the report, not yet confirmed, however, that a certain manufacturer of cigarettes offers a nice cemetery lot to every one who smokes twelve dozen packages of his cigarettes. Probably he wants to make the punishment fit the crime.

A YOUNG LADY'S PET PUG recently swallowed a threaded needle, and instead of administering a needle cushion, she had the animal etherized and the needle extracted by surgical means. She went to a great deal of trouble and expense to recover a needle that couldn't have cost any more than a cent.—*Norristown Herald.*

A REFINING PROCESS.—"I am somewhat astonished, Carper," remarked Bigbee, as he looked around the room, "to find that so great a book-worm as you are should possess so small a library."

"Ah, my boy," returned the other, "it takes a great deal of reading to find out what isn't worth keeping."—*Boston Saturday Gazette.*

DELICATE ATTENTION TO THE AUTHOR.—Daughter (*to mother*).—"Young Mr. Lightsome has just written a book, and has presented me with a copy." Mother.—"That is very nice, Laura." Daughter.—"Yes; and as Mr. Lightsome said something about making a call this evening, and I am very busy, I wish you would sit down and cut the leaves for me, and place it in a conspicuous place on the parlor table."—*Harper's Magazine.*

WHOLE No. 1685.] JUNE 15, 1889. [VOL. LX, No. 24.

PRICE, $5.00 PER YEAR. SINGLE NUMBERS, 10 CENTS. ESTABLISHED IN 1853, BY S. W. BUTLER, M.D.

JUN 17 1889

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

W. R. WARNER & CO'S

NEW AND RELIABLE RECIPES FOR PHYSICIANS PRESCRIBING.

In order to get the full therapeutic effects, physicians will please specify (WARNER & CO.) when ordering or prescribing.

☞The coating of the following pill will dissolve in 4½ minutes.☜

PIL: CHALYBEATE COMP.

(WARNER & CO.)

Nux Vomica is added as an ingredient to Pill Chalybeate to increase the tonic effect when desired.
Composition of each Pill.—℞ (Chalybeate Mass.), Carb. Protoxide of Iron, gr. 2½, Ext. Nuc. Vom. gr. 1-6.

DOSE—1 to 3 Pills.

Most advantageously employed in the treatment of Anæmia, Chlorosis, Phthisis, Scrofula, Loss of Appetite, etc.

PIL: ANTISEPTIC.

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ¼ gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic is prescribed with great advantage in cases of Dyspepsia attended with acid stomach and enfeebled digestion following excessive indulgence in eating or drinking. It is used with advantage in Rheumatism.

Prepared by WM. R. WARNER & CO.

PIL: ANTISEPTIC COMP.

(WARNER & CO.)

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid. 1 gr. Ext. Nuc. Vomica, ⅛ gr. Powd. Capsicum, 1-10 gr. Conc't Pepsin, 1 gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic Comp. are prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food.

Supplied upon physician's prescription by all leading druggists.

1228 MARKET ST., Phila. 18 LIBERTY ST., New York.

Combines the Virtues of Iron with Those of Salicylic Acid.

Solution Salicylate of Iron.

(AMER. PHARM. MFG. CO.)

An unfailing remedy in acute or chronic

RHEUMATISM

where deformity has not yet resulted.

This preparation has also been prescribed with great satisfaction in other affections where Salicylic Acid, Bicarbonate of Sodium and Ferrous Malate are indicated.

DOSE —Dessert to tablespoonful four times a day.

PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental and Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D

A PLEA FOR PROMPT INTERFERENCE IN ABDOMINAL DISEASES.[1]

BY J. M. BALDY, M.D.,
PHILADELPHIA, PA.

"Surgery becomes conservative when it tends to alleviate suffering without resorting to operative interference." "An element weakened by disease works viciously, it is true, or perhaps not at all; but if we seek to restore it to normal, we should not eliminate it altogether, but endeavor to heal the trouble, and thus restore the element to at least a measure of healthy action." "Carried into effect without exact diagnosis, and before the merits of a more conservative plan have been tried . . . it becomes a dangerous procedure, if not absolutely criminal." Such expressions are not of unfrequent occurrence in our medical literature. By the side of this, and in contrast to it, allow me to place with equal clearness, my own convictions. When an element weakened by disease, works viciously or not at all, and by so doing renders a patient's life miserable or eventually threatens that life itself, the man who stays his hand from eliminating that element, provided it can be done with reasonable safety, and rests satisfied merely with "a measure of healthy action," is, to say the least, not doing his whole duty to his patient. There are many cases of disease, calling for surgical interference, which threaten life, in which an attempt at an exact diagnosis or a trial of the merits of a more conservative plan of treatment becomes, with our present surgical knowledge, not only dangerous but almost, if not entirely, unjustifiable. Statements as strong as these must needs be qualified, that they may not be misunderstood; but it is equally necessary also to qualify such statements as those made in the interests of so-called conservative surgery. No one can appreciate the need of true conservative surgery more than myself, nor the impor-

[1] Intended to be read before the Medical Society of the State of Pennsylvania, June 6, 1889.

tance of men being thoroughly instructed and trained in the rudiments of our science; but this cry of conservative surgery is too often set up as a mere cloak of ignorance and cowardice. Our sins of omission are oftener greater than our sins of commission.

M. M.; æt. 17; single; family history good; had been in perfect health until present attack. Without any apparent cause she was seized with a pain in the abdomen, which increased rapidly in violence. She was seen the second day of the attack; belly tympanitic and swollen; much colicky pain in abdomen; pulse rapid; and some slight elevation of temperature; anxious expression of face; constipation for several days. Rectal enemata and other appropriate treatment were ordered. From unavoidable delay, the nurse did not give enema until next day. At noon a large solid passage followed the enema, and all the abdominal symptoms became better. Toward night vomiting, which had a suspicious smell, occurred. The patient was now made to drink large quantities of hot water and then vomit it. This gave great relief, and all the symptoms subsided, so much so, that for a second time operative interference was postponed. In the meanwhile the bowels could not be made to act again. Operation was decided on if the bowels did not again move, or if vomiting returned. During the next day the patient was remarkably bright, and in the afternoon ate largely and very greedily of corn-starch, enjoying it very much and retaining it all. Later she rose from her bed and emptied a pint vessel of the same food, retaining and enjoying it. She was apparently better in every way, and an operation was now thought to be unnecessary. Although the bowels had not been opened she said she felt as if they would be at any moment. It was presumed that, by the next day, she would be well over her troubles. At six o'clock in the morning she vomited two or three times, and then suddenly died. The autopsy disclosed a strangulation of the small intestine near the cæcum, by a band. A single snip of the scissors would have relieved it, and the patient would have been saved.

Here we have a picture which all of us have seen only too many times, and in the vast majority of cases we have seen it end in death. A case of intestinal obstruction is one of such a character that there is little room for hesitation. The disease is caused by such a variety of factors, and is so fatal in its ending, that to waste valuable time attempting an exact diagnosis or going beyond certain limits in the trial of the merits of a so-called conservative plan of treatment, is folly. Lusk never spoke truer words than when he said: "The resources of surgery are rarely successful when practiced on the dying." Why, with our past experience in these diseases, we should continue in the old beaten track of hoping against hope, only to see one valuable life after another slip through our fingers, without an effort to save them, I cannot comprehend. Mr. Treves states that in England, from this disease alone, over two thousand individuals die every year; and I think we are all agreed that in the United States we are equally unfortunate. Surely with such a frightful mortality as this staring us in the face, there can be little use for so-called conservatism. Here, at least, if this tremendous death rate is to be stopped, our only hope lies in bold, aggressive surgery. If a loop of intestine be caught under an adhesive band and strangulated, where one case may be relieved by purely medicinal treatment, ninety-nine will succumb. Of course, all cases of intestinal obstruction are not due to bands, intussusceptions and such causes; some are simply the result of fecal impaction, a slight temporary paralysis of the gut or some other cause amenable to medicinal treatment. If we knew that these were the causes, then it would be eminently right to persist for a considerable time in proper medical treatment. But this is just the point—we never know, or are never sure of the cause. The organic causes are so vastly in the majority, and the symptoms of all varieties are so much alike, that it is only safe to act always on the assumption that all are serious. Should a mistake be made, and an abdomen be opened for a case of obstruction due, for instance, to a fecal impaction, it would be a cause of regret that an unnecessary step had been taken. But our compensation would be even greater in such a case as this, than would be our chagrin. The diagnosis of an obscure and apparently dangerous case would be cleared up, and we could then proceed with confidence and certainty in our treatment, to a final cure. The harm done would be absolutely nothing. Such a mistake would however seldom be made and the number of curable cases, otherwise necessarily fatal, which would be reached and saved would over and over again triumphantly justify such procedures.

In the case cited above, the indications should have induced an early operation. The symptom of suspicious vomiting alone should have been sufficient to have settled

the question; and so it would have done, had not a passage of the bowels been obtained. From this point on, everything was in a position of uncertainty, and the old adage: "He who hesitates is lost," was again exemplified. The feces obtained were, of course, what was impacted below the seat of the obstruction, and that having come away, there was no more to follow. Fecal vomiting should always and invariably be taken as the limit of waiting in these cases. This having occurred once, opportunity should not be given for it to happen a second time, no difference what the other symptoms may be. It will be the rarest exception in the world that a mistake will be found to have been made. If relief has not been obtained within twenty-four hours by means of persistent and gently applied rectal enemata, the abdomen should always be laid open and explored, and whatever is found properly treated.

Two cases have recently come under my notice. Both were operated on after considerable delay, and, when the operation was finally done, a single stroke of the knife ended the strangulation and freed the bowel. In both cases several good passages occurred *per rectum* before the death of the patients. Both died from simple exhaustion. Here are three cases within a very short while, in all of which the subjects should be alive to-day, all young women and holding valuable places in the community. I could go back through the past three or four years of my experience and recall a dozen or more such examples, all of whom died for want of an early operation. The mortality of laparotomy for these diseases has been and is large—most frightfully so. Treves has collected 122 cases, with a mortality of over 63 per cent. According to Schramm the mortality in 193 collected laparotomies for intestinal obstruction is over 65 per cent. "Some of the patients were almost moribund at the time the laparotomy was performed, others were in a condition of profound exhaustion. In some there was general acute peritonitis, in others fecal extravasation had already taken place. Laparotomy has, indeed, been looked upon as a last resource instead of as a primary measure. This table shows in a graphic manner how serious is the delay, even of twenty-four hours" (Treves). An examination of the records shows very clearly that in cases in which the operation has been undertaken early enough, it is not a very dangerous one. In fact to those familiar with the present status of abdominal surgery, a simple incision into the abdominal cavity is a comparatively trifling measure. The great and only danger comes from delaying until the individual is past recovery.

These remarks as in regard to intestinal obstruction are equally true when applied to any other disease occurring in the peritoneal cavity. In a list of laparotomies collected by myself more than a year ago, there were 93 operations done for non-malignant diseases. Of these, eleven were followed by death. Of the eleven deaths—all after simple exploratory incisions—seven occurred for no other reason than that the operation was undertaken too late and the patient was in a dying condition. All the patients could have been saved had they been taken in hand in time. This element of time is being more generally recognized as of the utmost importance. We now accept it as one of the primary requisites in the Cæsarean section, and it is undoubtedly the one element which has chiefly contributed to raise that operation to its present successful status. If this be of such vital importance in the Cæsarean section, it is none the less so in cases of intra-peritoneal diseases. We daily see cases die shortly after an operation which should almost certainly have recovered.

Mrs. P., after an operation for an ovarian cyst, developed a purulent peritonitis. The case was temporized with day after day, because she became at times better and seemed on the way to recovery, in spite of the fact that the presence of pus was strongly suspected. She struggled on for three or four weeks, or more, and was finally given the benefit of an operation. Pus was found in large quantities. She made a brave fight for six days, and then died of exhaustion and sepsis. An operation one week earlier would undoubtedly have saved her.

X., medical student, was suddenly attacked with pain in his stomach and retired to bed. From the first there was well marked and exaggerated symptoms of peritoneal inflammation in the region of the cæcum. He was temporized with for four days, and was fed on morphia to ease his pain, with other so-called conservative treatment. He was told that there was not much the matter with him, and that he would get well. The attendant had seen many worse cases recover. A surgeon saw the patient the next day, and immediately operated. An ileo-cæcal abscess, with a badly diseased appendix vermiformis, was found. The patient died the same night.

Mrs. R. suffered for seven or eight years

with pelvic trouble, being treated conservatively (?) all the time. Suddenly she developed acute symptoms of intestinal obstruction. So-called conservative treatment was renewed. The patient went into collapse and an operation was advised. The consultant physician objected. The patient recovered from her collapsed condition, and in twenty-four hours had a similar attack. An operation was even yet opposed. The patient made a partial recovery from this second collapse, only to fall into the same condition for a third time. At this late hour an operation was agreed upon, and disclosed large pus tubes, with intestines so tightly bound upon them as to strangulate them. Death followed in twenty-four hours.

Miss L., suffering plainly referable to calculus, and a large stone, immovably fixed in one of the ureters, plainly felt by vaginal examination. Whole cause of trouble clearly recognized and the impossibility of spontaneous delivery realized. Patient in good condition and willing for anything to gain relief. Allowed to drift on under hopeless conservatism until operation was impossible.

Mrs. C., clear history and diagnosis of extra-uterine pregnancy, with rupture of the gestation sac. Condition of patient fully realized and yet temporized with. Operation after two days delay, and, naturally enough, death followed from exhaustion.

But why should I cite more illustrations? You have all seen them and fully realize the truth of the statement that where one individual is killed by an unnecessary operation, hundreds die for want of one. An exploratory operation, with the patient in good condition, is a very harmless thing; and those of us in future, who allow patients to die from well marked intra-abdominal disease and stand in the way of an operation, can no longer hide our want of skill and knowledge under this false cry of conservatism. Bantock and Price have both entered strong pleas for early interference, especially in ovarian tumors. It is folly to wait "until the heart and lungs, digestive organs, kidneys, bladder and rectum, no longer discharge their functions without disturbance," or "until the general health has become impaired," or "until all other means of relief have failed, and the patient's health is giving way under the extension of the disease," or "until the patient is failing in strength and becoming emaciated, depressed and nervous," as advised by many prominent men and teachers. In the words of Bantock, I am not aware that there is any operation in the whole range of surgery, in any other part of the body, *that must be a matter of necessity sooner or later*, if the patient's life is to be saved, in which it is considered advisable to await this contingency. Many cases are being refused for operation by operators, because of their having been left so late and handled by a more conservative plan of treatment until it is too late for surgery to have even a half chance of success.

I have in my practice at the present time half a dozen women, all of whom have run the gauntlet of the dangers of peritonitis two or more times and have come out of each attack in a much worse condition than they were before. They all refuse operative interference because they know, or have been told of, some friend who has died after an operation. Of these deaths, two to my personal knowledge were hopeless cases and should never have been touched with the knife. The consequence of the conservative treatment which had encouraged them on to death, with pus tubes in their abdomens, is that a dozen or more women are gradually dying for want of proper treatment. When a patient is dying it is simply a blow to good surgery to attempt any operation whatever.

In the words of one of Philadelphia's most brilliant gynæcologists: "The day is coming when Abdominal Surgeons will be the most arbitrary of men and will refuse to interfere, when called in only at the eleventh hour, merely as a last resource." If surgery has any place in intra-abdominal diseases it most emphatically is not as a last resource, but as a primary measure. As a last resource, abdominal surgery, the world over, has proven a dismal failure; as an early and primary procedure, there is no branch of our art which has achieved such brilliant and lasting results.

We have only to look at the records of the prominent gynecologists, to see who have, and who have not, accepted this principle of early and timely interference. It is unnecessary to go beyond this city to find such a man, one whose work has made him an ornament to our profession; and Dr. R. S. Sutton can rest well content that, in his last thirty abdominal sections, for various diseases, he has saved every one of his patients.

As an end of this short and imperfect plea for the necessity of prompt and intelligent work in abdominal diseases, I cannot do better than quote the words of Dr. John B. Roberts, in his address to the Philadelphia

Academy of Surgery, 1888: "Above all, the successful surgeon is a man of action. Experience and knowledge must be there, but they are of little value without action. Inexperience and ignorance are the parents of timidity and recklessness. To avoid these dangers he must have experience and knowledge, which though power, are mere possibilities until used as a source of deeds. The victory of battle is to the leader who does most, not to him who knows most. The true surgeon often takes the offensive, which is for the intrepid alone; but the weak surgeon falters and lets death come because of his offensive hesitancy."

PHYSICAL EDUCATION.

BY C. F. McGUIRE, M.D.,
BROOKLYN, N. Y.

At present the subject of Physical Education is engaging the attention of educators to an extent that is surprising. When we consider its importance, however, we are more surprised at its almost universal neglect hitherto. The ancients paid great attention to this department of education, and, moreover, did not consider physical strength incompatible with intellectual vigor; on the contrary, their idea of the subject was aptly expressed by the axiom: "a sound mind in a sound body."

It is strange that this important fact was lost sight of by modern educators, and that we should only now be attempting what was an accomplished fact hundreds of years ago. We have had physical training, but usually mercenary in intent, and not in connection with a regular course of study. Yet people have always admired the trained athlete, and no doubt would have taken up the subject, if they but knew how to go about the matter. The trouble has arisen, in a great measure, from the fact that the men who were accepted as the exponents of this art, were not as a rule men whom fathers of families would care to have their children associated with.

Comparatively a short time ago, a body of educated men took the matter up, and, as a consequence, we are beginning now to see in our schools and colleges the fruits of their laudable efforts. It is for this reason that Dr. Anderson, of the Brooklyn Normal Training School for Physical Culture, has been trying for some time past to get the medical profession interested in this matter, especially the younger members, who have more time at their disposal, and to whom it offers a lucrative business. Dr. Anderson reasons that this department of education rightly belongs to the medical profession, as its members are the only ones that are qualified, both by training and education, to fulfil properly the functions of a teacher of this art.

I would suggest that doctors before engaging in this profession should master some one of the various systems now practised, as by so doing they will have a foundation to start from and also save themselves much trouble and anxiety. After they have acquired the necessary ground-work, they can then begin originating, improving, or correcting, as they may find necessary.

There is a great deal to be accomplished in this department—many household gods to be destroyed, many errors to be corrected. This has been well illustrated in the case of Dr. Leuf, of Philadelphia, whose articles in the MEDICAL AND SURGICAL REPORTER have been quite a revelation to many. The doctor has ably shown that many popular works on this subject are, to say the least, fallacious in their teachings and erroneous in their deductions. As an example of erroneous teaching, we have only to take up the subject of so-called abdominal breathing. This method is claimed by many excellent teachers of music to be the only true one, and that any other will surely lead the victim into consumption or else destroy the voice in time. If any one will take the trouble to investigate for himself or to read his works on anatomy, he will be quickly convinced that forcible expansion of the abdominal walls must lead, in the end, to injury. What should be aimed at, in the art of breathing, is a flexible condition of the thorax; and the muscle which will bring about this flexibility, principally, is the serratus magnus. The diaphragm will take care of itself; for if the ribs are well drawn out by the serrati muscles, it will quickly descend, without any effort on the part of the subject.

Another point, which has been overlooked, is what we will term: individualizing the person—a method always adopted by the successful physician when engaged in diagnosticating disease. By this method the strong points of the person in question can be ascertained and the weak points developed. Most men are weak in the abdominal region, and for that reason this should be the part first attended to. And, moreover, in my opinion, it is the most important part of the body to be developed, for various reasons, best known to physicians. The muscles

of this part of the body, together with the serrati muscles, should be plainly visible to the naked eye; and when a man is thus developed, the developing of the rest of the body is accomplished with comparative ease. The main object should be the uniform development of the whole body, never exercising one or two parts at the expense of the others. This point can be readily proven by a visit to one of the German "Turn-Schools," or—as we call them—gymnasiums. There one can see pupils who are experts in certain feats, but whose general make up is not flattering to the system.

When a man is once properly developed, he will remain so, provided, he practises a correct carriage of body and a proper method of breathing. This is well illustrated in the person of a certain Mr. Checkly, of Brooklyn, who is at present engaged in teaching physical culture. This man claims to have taken no special exercise previous to last January, for the space of ten years; yet at the end of that time he was able to handle his body with far greater ease than many men who were engaged constantly in gymnasiums.

What we need in this country are institutions devoted to rational gymnastics, also to the study of physiology, anatomy, hygiene and instruction in the art of cooking; for it must be remembered that the ordinary trainer knows what kind of food is necessary for his pupil. This instruction is vital; for without the proper fuel, no matter how good the machinery, we cannot get the same results. If a man, or woman, could show a diploma from an institution, conducted on these principles, then we might expect to see men and women who would not only be a credit to themselves but a great gain to the state. As a result of such teachings men would have more regard for their bodies and be less likely to abuse them by vile practices; and society in general would put on a different aspect. Instead of crowding rum-shops and other places of evil resort, they would flock to the gymnasiums or the open fields, there to exercise their new found powers, which, instead of making them feel wearied or exhausted, would, on the contrary, better prepare them for the successful prosecution of their business.

It remains with the medical profession especially, to bring about this grand result, and also to interest philanthropists in a scheme that will be far more beneficial to humanity than the erection of a thousand hospitals.

TUBERCULOSIS OF THE TESTICLE IN A CHILD NINE MONTHS OF AGE.

BY CHARLES B. PENROSE, Ph.D., M.D.,
PHILADELPHIA.
SURGEON TO OUT-PATIENT DEPARTMENT, PENNSYLVANIA HOSPITAL.

The following case is of interest on account of the very young age of the patient, and the complete recovery after excision of the diseased testicle.

A. B., black, nine months old, was brought to the Out-Patient Surgical Clinic of the Pennsylvania Hospital, during the writer's service in January, 1889. The patient's right testicle had begun to swell five months before, and an abscess had formed three months later and ruptured through the scrotum. When the child was first brought for treatment, there was a fungous outgrowth about one inch in diameter on the right side of the scrotum, attached to the right testicle, which was enlarged to the size of a pigeon's egg. There was a profuse purulent discharge, which had produced many superficial ulcers on the buttocks and inner aspects of the thighs.

The spermatic cord was knotty and about one-third of an inch in diameter. The left testicle was healthy. There were scars on the neck caused by previous suppuration of the submaxillary lymphatics. With the exception of the diseased testicle there was no sign of active tubercular disease. The mother was healthy and had had nine healthy children; the father had had a cough for several years.

The fungous outgrowth, the right testicle and the thickened portion of the spermatic cord were cut away; the indurated and thickened edges of the scrotal opening were removed; the cavity was thoroughly dusted with iodoform, a rubber drain was introduced, and the wound closed. The attempt to obtain primary union, however, was not successful, and the wound healed by granulation.

Examination of the removed gland showed that there was complete destruction of the epididymis by tubercular abscess, and that miliary tubercles were scattered throughout the body of the testicle. When the child was last seen, in April, 1889, there was no sign of tubercular disease in the right cord or in the remaining testicle, and the general health was fair.

In well-recognized general tubercular disease of the testicle, the gland should always

be removed if the disease has not extended beyond the reach of the knife. If rectal examination shows that there is involvement of the seminal vesicles, the prostate or the bladder, removal of the testicle will not delay the course of the disease. The danger of such extension, and of extension to the other testicle, when operation for tubercular disease of the testicle is delayed, should always be remembered; and also the danger of general tuberculosis originating from this focus. Dr. E. H. Monks, in the *British Med. Journal*, Dec. 27, 1884, reports a case of tuberculosis of the testicle in a child five months of age, in which the removal of the gland was refused by the parents, and the child died soon afterward of general tuberculosis. And Laennec (*Gazette Méd. de Nantes*, 1886–1887, V, 117) reports a case of general tuberculosis which followed the late removal of a tubercular testicle. In localized tuberculosis of the testicle, even when an abscess has formed and a sinus exists through the scrotum, recovery occasionally takes place, either without surgical interference, or after destruction of the tubercular focus with the curette or cautery. But when the disease is generalized, the gland becomes functionally useless, and the dangers of extension and of general tuberculosis demand its removal.

1331 Spruce St.

TWO MONTHS IN THE HOSPITALS OF PHILADELPHIA.

BY GEORGE R. DEAN, M.D.,
SPARTANSBURG, S. C.

A busy practitioner, especially if located in the country, has but little time, and often less means available, to leave his labor and visit the great medical centres of our country. There are always a few old cases on hand, and a few new ones expected which will deter him from appointing a day to start, so that his trip North, South, or East, as the case may be, is delayed from time to time, until he finally gives up and plods on in the same old rut. Occasionally, however, one is found who in sheer desperation breaks over all difficulties, as did your correspondent, and drinks afresh at the fountain's source, so pleasant to one who is isolated from medical societies and opportunities and all sources of information save from his own limited and often sad experiences. The reports of those who have returned from Philadelphia have not always been the most encouraging or reassuring to those who wish to return to the city of their Alma Mater. What they want and need most, is clinical work, with short lectures descriptive of the various diseases and treatments, and opportunity to assist personally where it is possible. This, and this alone, can give them the information they most need.

It has been said that physicians and surgeons occupying positions in the hospitals and dispensaries of Philadelphia, which would enable them to do much in this direction, have not been as generous with their courtesies to the profession as those occupying similar positions in other cities. For this reason many of our Southern physicians have gone elsewhere to refresh their minds in medical knowledge when their inclinations were otherwise in favor of Philadelphia. Be this as it may, my own experience in this respect has been altogether different. I visited many hospitals and dispensaries, and received the most genuine hospitality and courtesy from both chiefs and assistants, in each and every instance. I therefore gladly record my evidence on the other side of the question, for a more generous, kindly interest could not have been shown to friend or stranger than was extended to me by those with whom I came in contact, during my two months stay in that city.

A man who expects to receive courtesies must himself be courteous, and when men complain of mistreatment at the hands of others, it is but just to inquire if they have been without blame themselves.

Some of the best clinics in Europe have been closed to visitors by the indiscretion of a few men who forgot themselves and the obligations due those whose courtesies they were enjoying. I saw in Philadelphia much of advanced surgery and gynecology, and it is my belief that our countrymen can find all they want and need here in the way of knowledge and skill in every department of the healing art, and men with nerve and brain to demonstrate them satisfactorily. A long trip to Europe, therefore, with a possibility of snubs from those whose skill is equalled if not exceeded in our own country, is not necessary to those who wish to keep abreast with the advance of the profession. I believe if a physician will go to Philadelphia with the earnest desire to see and learn, and will deport himself as is becoming a true gentleman, he will find physicians who are ready, willing and capable to give him just what he wants.

The improvement in the treatment of the diseases of women has been greatly advanced

in the last few years. Antiseptics truly revolutionized this field of the physician's work, and now asepsis, in the hands of some of the most expert and advanced operators, has superseded this. Operative treatment of tubal and ovarian diseases is now a well-established procedure, and as now performed by a few of the profession gives results almost beyond belief, as witness the records of Dr. Goodell, Dr. Charles B. Penrose, Dr. Joseph Hoffman, Dr. John B. Deaver, Dr. M. Price, and Dr. Joseph Price with his 63 consecutive cases without a death. Through the kindness of Dr. Goodell, I was permitted to witness and assist in several ovariotomies in his private hospital. Through the kindness of Drs. M. Price and Hoffman, I saw many cases in their private practice—the former showing me several cases of great interest and permitting me to assist him in several of them. To Dr. Joseph Price I am indebted for the many advantages afforded by my visits to the Philadelphia Dispensary and the Gynecean Hospital. This hospital, in charge of Dr. J. Price and Dr. Charles Penrose, is a model in its way. It is new and small and lacks many conveniences of some other hospitals, but the lack of these is more than counterbalanced by the skill and enthusiasm of its chiefs, and their determination to achieve a success for it second to none in the world. It already stands at the head of such institutions in the United States. Their success is very gratifying, both to themselves and to the friends of the institution. I witnessed many operations while there—abdominal sections, and plastic operations upon womb and perineum—success in every case followed. I have seen pus tubes as large as small intestines, adhesions so great that the bowel would tear before the adhesions would break, and all anatomical relations obliterated in the pelvis; and yet these patients made an uninterrupted recovery. As to the results following ovariotomy for tubal and ovarian disease, I made many inquiries of the patients themselves, through the kindness of Dr. Price at the Philadelphia Dispensary. The verdict in every case was the same: the patients had either been cured entirely or were passing through the phases of a premature menopause. Not one single woman did I see, who did not express herself as being greatly benefited by the operation. So, from being a skeptic, I became a believer in surgical interference in these troubles, which unfit a woman for performing the ordinary duties of life; and I shall devote the balance of my life to this special department for the relief of suffering womankind. In the Gynecean Hospital there are no antiseptics used in abdominal operations, but the asepsis is perfect, as far as human efforts and skill can make it so. The whole staff, from nurse to chiefs, is in full sympathy with its chief design; and success crowns their labors.

My experience in other dispensaries was very pleasant. To the physicians who extended me so many courtesies and so much kind consideration, I am under lasting gratitude; and I assure them that I will not soon forget their pleasant faces. Indeed, Philadelphia has hosts of good and true men in the profession, who are ready and willing to assist those who are truly and honestly trying to gain information.

HEMORRHAGE FROM THE UMBILICUS.[1]

BY H. F. WILLIS, M.D.,
PRESTON, MD.

The recent occurrence in my practice of a case of fatal hemorrhage from the umbilicus, being an event so rare, led me to give some attention to the literature of umbilical hemorrhage. I was surprised to find all of the old authors, whose writings I had an opportunity to consult, were silent upon the subject. A gentleman, to whose paper I am indebted for most of the information upon which this paper has been based, says that Cazeaux, Ramsbotham, Leischman and Lusk say nothing on the subject.

Dr. Joseph S. Gibb, of Philadelphia, in a paper read before the Philadelphia Clinical Society, March 28, 1884, and published in the *Medical Times*, of that city, May 17, 1884, has tabulated all the cases upon record up to that time. Various authors had reported, up to 1881, 236 cases. Between 1881 and 1884, Dr. Gibb found 5 more cases reported in the medical journals, the last of which was seen by himself. This record proves the rarity of umbilical hemorrhage; yet it is liable to happen at almost any time.

Following the classification of Dr. Gibb, umbilical hemorrhage may be divided into three classes: First, hemorrhage from improper ligation of the cord; second, hemorrhage from traumatism; third, hemorrhage of spontaneous origin.

The first variety, or hemorrhage from improper ligation of the cord, is liable to

[1] Read before the Caroline County Medical Association.

occur at any time from carelessness on the part of the attending physician or the nurse. It is especially liable to occur when the cord is large and full of gelatinous matter; for, as it becomes smaller, the ligature is loosened, even when it has been properly applied in the first place. It is important to examine the ligature around the cord after the child has been dressed, to be sure that such a disagreeable accident may not occur. If you, Mr. President and gentlemen, have always been so fortunate as to escape being roused from a delightful sleep by the announcement that the baby was bleeding from the navel, you are more fortunate than the speaker, who remembers regretfully one such incident in his professional career. No life was lost, but it was an occurrence certainly not to be proud of. I think this form of hemorrhage is rarely fatal. Proper tying of the cord is the remedy.

The second variety of hemorrhage is occasioned by unnecessary handling of the infant. I have seen some poor little babies pretty roughly treated, and it is possible that after the dressing has been completed that undue pulling of the clothing and bandage might produce hemorrhage before the cord has had time to dry sufficiently; and any tearing of the cord near the umbilical surface might set up an alarming bleeding. If the part of the cord torn is too near the surface of the abdomen to be tied, the dependence for treatment would be upon styptics and compression.

The third variety—hemorrhage from spontaneous origin—is the variety which most concerns us. The hemorrhage may occur at almost any time. It generally sets in, I believe, about the time the cord begins to come away. You have all watched the drying up of the cord—undoubtedly a physiological process in ninety-nine cases out of every hundred. It begins at the outer end of the cord and extends toward the umbilicus; and, unless nature has been interrupted in her work by meddlesomeness or disease, a few days suffice to bring the cord away as a foreign substance, leaving a clean healthy surface to heal as rapidly as possible with the mildest and simplest dressings. It occasionally happens that the babe will bleed two or three days after birth. Examination will then reveal the fact that the outer extremity of the severed cord has undergone the true process of drying, but that the cord next the umbilicus has undergone softening, and you witness a sphacelated or gangrenous condition, with blood oozing from the edges of the umbilical depression. Fetor and softening warn you that the usual physiological process has been converted into a pathological disturbance of a serious character. The oozing may have begun slowly; styptics and pressure may control it for a time. Let it not be forgotten that it is very liable to recur in a short time. The blood is generally thin, watery, and lacking in the power to coagulate firmly enough to satisfy you that the danger is over.

As to the causation of this form of umbilical hemorrhage, it is evident that there is generally something at fault in the constitutional condition of the child, either hereditary or congenital. Jaundice is frequently found associated with this form of hemorrhage, and hence it is sometimes set down as the cause. Is it not more than probable that both symptoms—hemorrhage and jaundice—depend upon some blood dyscrasia? Dr. Gibb believes this to be the case, and argues forcibly in favor of his belief. I am led to believe with him that hemophilia is generally *the* disease of such infants, and that the jaundice is only "an indication that the liver is not receiving its proper healthy pabulum, and hence refuses to carry on its functions properly."

In my own practice, I now remember only two cases. The first occurred in January, 1884. The second day after the birth of the infant, I was hastily summoned to arrest the bleeding. The blood was oozing from the outer surface of the umbilical depression quite freely. The cord was nearly completely separated close to the belly. It was soft and fetid. The child was jaundiced. In this case the mother was young, strong and healthy at that time. I think she still remains so, although some of her relatives on the mother's side—her mother also—had died of phthisis. The child recovered, finally, but I think the hemorrhage returned two or three times.

The second and last case occurred in March last. On March 7, I was called, in the absence of the family physician, to attend Mrs. A., who was in labor. Upon my arrival, I found that the child had been born and dressed an hour before. As I approached the bedside of the mother, I was struck with her anæmic look. The placenta not being delivered I feared hemorrhage, but it was only the ordinary appearance of the woman. Inquiry elicited the statement that before her pregnancy she had had two profuse hemorrhages from the lungs. I saw her on the 8th; both mother and child were apparently doing well. On

the morning of the 10th, I was hastily summoned to see the child. When I reached the house I found it almost in a dying condition, the clothing saturated with blood. I lowered its head and shoulders, and proceeded to remove the bandages and clothing. The cord was ready to come away; the end farthest from the umbilicus had dried in the physiological manner; the portion nearest the abdomen was soft and fetid—in a condition we might properly call soft gangrene. The child was thoroughly bloodless. With the anæmic color the icteric hue was marked. The child continued to moan for several hours, but never rallied. A styptic and compress prevented any further hemorrhage. Was this a true hemophilia, or only a manifestation of the hereditary hemorrhagic diathesis?

How shall we treat such cases? The result in my first case is in favor of the use of styptics and compression. Whether I gave calomel to the child or not I do not now remember. The styptic used was Monsel's solution. The second case was necessarily fatal at the time I saw it. I do not know that it should discourage us from attempting internal treatment, if the case is seen in time.

In this paper I claim little of originality. To Dr. Gibb, of whom I have frequently made mention, belongs the credit of bringing the subject prominently before the profession. If to you, Mr. President and gentlemen of the Society, I have succeeded in investing the subject with some degree of the interest which I have experienced while devoting some hours to the preparation of this paper, I shall be abundantly repaid for the time and labor.

—It would be an excellent idea, says the *Manchester Union*, if physicians of the present day would invent some other reason for about all of the deaths which occur nowadays than the cheap fraud, "heart failure." This might not be of serious moment were it not for the fact that hundreds of people are being nearly frightened to death by the constant use of the cause for sudden deaths, and many people who are sick and necessarily have some heart symptoms are kept in constant terror by reading or hearing in other ways of death after death by heart failure. There are probably no more deaths from heart failure in these times than heretofore, but a new cause for death has been coined and the nervous and timid are being severely injured by it.

REPORTS OF CLINICS.

PHILADELPHIA HOSPITAL.

CLINIC FOR DISEASES OF CHILDREN—DR. STRYKER.

Hare-Lip and Cleft-Palate.

Here is a case that tells you the whole story. You will see at once that it is hare-lip, and that it came very near being double. In addition, there is a deficiency in the palate on each side, leaving quite a prominent intermaxillary bone in the middle. The union is complete behind. These cases, of course, call for operation. The hare-lip should be operated upon first, because the bringing together of the lip has some controlling action over the gap in the roof of the mouth, so that when the staphylorrhaphy is performed when the child is five or six years old, there will then be a much smaller chink in the palate to close up. The time for operation is a question about which surgeons are a little unsettled; but the best time is when the child is two or three months old, unless there is some pressing need of operating earlier.

The operation consists simply in freshening the edges, bringing them together, and liberating the lip from its attachment to the mucous membrane covering the jaw. Some surgeons recommend an elliptical, others an angular incision in the lip, the object being to avoid a little depression that is likely to occur just at the point of union at the free border of the lip. In this case the left intermaxillary bone projects forward, and by pressing against the lip may prevent its uniting. Sometimes the prominent portion of the bone has to be removed so as to allow the cut surfaces to be brought together.

Non-Inflammatory Diarrhœa.

I have three or four little patients whom I wish to bring before you this morning, to introduce the subject of affections of the alimentary canal, which, as the season advances, will become more common. Irritations of the alimentary tract in the spring season are due generally either to cold, to some fault of digestion or to some similar cause, and are certainly not due to heat, as they are apt to be during the summer season. We will consider this morning only the mild diarrhœas of children, and it might be well to call them the non-inflammatory diarrhœas, they are so evanescent.

The attack occurs so suddenly that there are no marked premonitory symptoms. At the time of the attack there may be a slight increase of temperature and an acceleration of the pulse, a certain amount of thirst, indisposition to eat, and there may be also a furred tongue or a patchy tongue—red in spots and white-furred in other spots. Such a tongue always indicates some disturbance of digestion. The attack is usually of short duration, although it may run into a more marked enteric irritation. If the child should die, there would be found very little to account for it except a slight engorgement of the blood-vessels of the intestine.

In institutions like the Philadelphia Hospital, we are liable to have cases of this sort at all seasons of the year, because the large majority of children in our nurseries and foundling wards are artificially fed. But even with nursing babies the milk may be irritating, and it will then give rise to just the same conditions as are found in babies artificially fed. If the breast-milk is persistently irritating, resort to artificial feeding, or, if the family can afford it, get a wet-nurse.

Here are two diapers containing the stools. You see a certain amount of lumpy matter, consisting of curds. Here in spots is a greenish-color, due to acidity. This is the result, possibly, of feeble stomach digestion in these children, and the consequent passing into the intestine of undigested particles, which give rise to intestinal indigestion and produce a diarrhœa. The number of passages varies from three or four to eight or ten in the twenty-four hours.

The best treatment consists in getting rid of the exciting cause, and, for this purpose, a mild purgative is indicated. The *Mistura Olei* of the old Dispensatory, consisting of a little castor oil, a few drops of oil of peppermint, and mucilage of acacia, is a good combination. Small repeated doses of castor oil will do better than a single large dose. Spiced syrup of rhubarb is a remedy that is in every household, and is used for just such a condition. Avoid over-feeding. A little chalk mixture may be necessary as an astringent later. The important part of the general treatment is so to regulate the child's diet as to prevent a continuance of the condition. A little bismuth or pepsin, or a drop of brandy with the meal, will stimulate digestion and allow the child to become properly nourished. As a rule, the child suffers very little pain, so that anodynes are seldom necessary.

Special Correspondence.

LETTER FROM CHINA.

As Canton City is on the great highway around the world, and is what we might term the New York of China, there are naturally a great many tourists and travelers who visit us. The large medical Missionary Hospital for the Chinese is nearly always visited by those who come to Canton. I have thought it might prove interesting to answer, through the pages of the Reporter, a few of the many questions asked by medical men and those interested in medical work in China.

Are there any native schools in China where medicine or surgery is taught? There are none. Native doctors there are in abundance—self-made doctors, they might be called; for they have never been under any system of medical education. No license of any kind is required of those who practise medicine. With the exception of a few native drugs, they are ignorant of the action of the many (supposed) remedies that they use. One wishing to qualify himself for the practice of medicine must be at least forty years of age, and generally a period of four or five years is spent with a native doctor, or perhaps part of the time in a native drug shop. It is indeed strange that, while much of their knowledge is derived from practical experience, yet their views on the whole subject are most erroneous.

Do the Chinese practise surgery? Not in any way. They stand aloof from the surgeon's knife, and do not attempt the simplest operations. Even those who have studied our western science of medicine and surgery find a great barrier to their practice of the same; for, should any accident whatever happen to a patient under their care, they would most likely have to pay heavy damages; and, should the case terminate fatally, the doctor would probably lose his head.

Do native physicians attend obstetrical cases? They do not. They may write prescriptions for certain cases, but are never in direct attendance. As a rule, a midwife is employed. If not, the ever-present mother-in-law assumes charge of affairs. The Chinese have no mechanical appliances to use where complications arise, and they have no knowledge of the mechanism of labor. There is a wide field here for the gynecologist and obstetrician. The foreign doctors from the hospital are very

frequently called where complications arise in confinements, and little attention is paid to sex. The male physician is generally as readily admitted to the homes in such cases as the female physician is.

Do the Chinese readily submit to operations and are their powers of endurance good? As a rule, the Chinaman has implicit faith in the foreign surgeon, and is about as ready to go on the operating table as to lie down on his bed. So far as their nervous system is concerned, they are far less liable to suffer from shock than the European is, and their powers of endurance in severe operations seem to be much greater.

Are the diseases and surgical affections met with of much the same nature as those met with in America? So far as Southern China is concerned they are, generally speaking, the same. The eruptive fevers, except small-pox, are seldom met with. Pneumonia and diphtheria are rarely seen or heard of. Leprosy and elephantiasis are common, and Asiatic cholera is present every summer. The field of surgery is wide and almost any variety of surgical affection may be met with. Tumors, both malignant and non-malignant, of all varieties, are met with very frequently. Two wards of the Canton Hospital are set apart for patients who have urinary calculus, and there are from three to fifteen cases constantly present the year round. Calculus is found at any age, from that of the child one year old to that of the old man of eighty. This affection, however, is confined to a few districts near Canton City, and is very seldom met with in other places.

Much more might be said on these various points than can be included in a letter.

The first of the year 1887 there was organized "*The Medical Missionary Association of China.*" It has for its object—*First.*—The promotion of the Science of Medicine and Surgery among the Chinese, and mutual assistance derived from the varied experiences of medical missionaries. *Second.*—The cultivation and advancement of mission work and the science of medicine in general. *Third.*—The promotion of the character, interest and honor of the fraternity by maintaining union and harmony of the regular profession. All members are graduates of recognized regular medical colleges, and persons of every nationality are eligible for membership. The representative organ of this association is "*The China Medical Missionary Journal,*" which is published quarterly by Kelly and Walsh, Shanghai; price, two dollars per year. Those interested in the progress of western medical science in the east will find a store of information in this journal.

One can scarcely imagine the untold value of Western medicine and surgery to the Chinese. They may hate the foreigner and all that belongs to him *except* the healing art—that they always welcome. It has been the entering wedge for Christianity and has done more to open up China to our western civilization than all the cannon of Europe.

Periscope.

Mumps and Double Orchitis.

In June, 1887, Dr. Manbrac noted an interesting case which occurred at Bizerte during an epidemic of mumps. A man, 45 years old, was suddenly seized with painful swelling of the left parotid gland. For four days there was much tumefaction, and the patient was feverish. On the sixth day the swelling had slightly diminished, but orchitis of the left testicle set in. The complication lasted five days; during that time the parotid swelling became smaller. The patient then appeared to be convalescent. On the sixteenth day, however, the patient complained of much pain in the right testicle. The entire gland appeared to be involved in very acute inflammation. By the twenty-fourth day the patient was nearly well; the buccal mucous membrane remained somewhat œdematous, but the patient could open his mouth and masticate food without pain. Both testicles seemed to have returned to a perfectly healthy condition. Dr. Manbrac, writing in the *Gazette Médicale de Paris*, notes that the epidemic occurred amidst a population of 7,000; nearly ninety children were attacked, yet the above patient was the only one older than 20 who suffered from mumps. He lived in a house where a child aged 6 was laid up with mumps. His teeth were remarkably sound, and his health when attacked was good. He had no trace of syphilitic, gonorrhœal, or malarial taint. The case is of distinct interest, as the undoubted occasional association of mumps and orchitis is as interesting as the singular association occasionally observed between parotitis and injuries of the abdomen or abdominal section.—*British Med. Journal*, Feb. 16, 1889.

Influence of Carlsbad Water on the Secretion of Uric Acid.

At the meeting of the New York Academy of Medicine, January 15, 1889, Dr. S. LeClercq, of Carlsbad, Germany, said he had made careful experiments on himself to determine whether, as had been supposed, the secretion of uric acid is lessened by drinking freely of Carlsbad water. With a uniform diet and taking increasing doses of the water, he found the amount of uric acid unaltered, as compared with the amount noted in the five weeks previous to taking the water. He has found that on a fixed diet the daily amount of uric acid, nevertheless, varies. Niemeyer has stated that this variation depends on unknown changes of action in the internal economy. He believed that in the future the influence of any drug on the production of uric acid would be found to have no special relation to its value in the treatment of gout. Our theories as to the nature of gout and the action of Carlsbad salts must both change. He has found Carlsbad water acting in several ways, some of which are: 1. The condition of the patient is improved through its causing the production of better blood (without any solution or dissipation of the tophi). The taking of warm water of itself acts favorably by diluting the fluids and washing out the channels of the body. 2. In certain cases the gouty diathesis is not perceptibly modified. 3. In other cases the water seems to lessen the synthetic formation of uric acid. 4. It often acts on other anomalies of function, and improves the general health. The digestion is in some cases improved, or deleterious by-products are taken up and excreted more rapidly. Perhaps the topical effect of the water on the stomach explains much of the benefit obtained. The exercise, bathing, pure air, and change of surroundings also must exert considerable influence on the peristalsis and circulation, and thus increase the general tone of the body.

Dr. F. N. Otis spoke from his own impressions derived from a recent prolonged stay at Carlsbad, and from the results obtained by sending patients there. He had gone to Carlsbad himself to obtain relief from what was either a gouty or a nervous dyspepsia, with mental depression and inaptitude for work. His diet while there had contained little sugar or starch, but an abundance of meat, with a little bread and claret. Although he had taken but little exercise, he had lost a pound in weight every day for a month. A feeling of debility had been noticeable during his stay at the Springs, and had continued for about a month after his departure. It had then slowly disappeared; he had regained flesh, and had had no return of digestive troubles. He thinks the patients who can anticipate benefit at Carlsbad are those whose sickness is due to free living and too little exercise. When a patient can not be sent to Carlsbad, he recommends the giving of remedies which act on the skin and liver; also abundant exercise. Mercury he regards as a most valuable remedy; it has relieved the condition when a visit to Carlsbad has failed to do so. He gives one, two, or even three grains of calomel a day, and does not find the system deteriorated by it. He has found that when there is Bright's disease, with abundant albumin, the Carlsbad waters depress the vitality, and are the reverse of beneficial.—*N. Y. Med. Journal*, March 9, 1889.

Hegar's Sign of Pregnancy.

The most conclusive signs of pregnancy in the first three months are to be found in the changes which take place in the size, shape, and consistence of the body of the uterus. These changes are the natural result of the lodgment and growth of the globular ovum in the uterine cavity. The body of the uterus bulges out as the ovum develops, its lateral borders become rounded, and there is a distinctly marked bellying of the anterior wall. After from four to six weeks' development this segment of the uterus presents in a very perceptible degree the characteristic elasticity of the fluid cyst which it contains. To the well-trained touch the bellying of the lower segment of the uterus, especially its anterior wall, and its fluid elasticity, are sufficient for the diagnosis of pregnancy in a large number of cases from the fourth to sixth week. These signs are obtained by the "bimanual" touch, as practised in ordinary gynæcological examinations.

To the signs above mentioned, Hegar has added another. This consists in the marked softening and thinning of that portion of the corpus uteri immediately above the cervix, especially as obtained by Hegar's method. His method of examination is as follows:

A preliminary distention of the rectum with water may be necessary to facilitate the manipulation. Chloroform may be used if required. Depressing the uterus with one hand over the abdomen, pass the index finger of the other hand into the rectum, up through the third sphincter, and press the finger tip

against the posterior wall of the uterus immediately above the utero-sacral ligaments. Pass the thumb of the same hand into the vagina and bring it in contact with the anterior wall of the uterus just above the cervix. The intervening tissues may in most cases, during the last half of the second month, be compressed by the grip of the thumb and finger almost to the thinness of a visiting card. This compressibility of the lower uterine segment thus obtained is Hegar's sign. It has been confounded by writers with the before-mentioned changes in the uterus, from which, as a sign of pregnancy, it is entirely separate and distinct.—*Brooklyn Med. Journal*, March, 1889.

Fecal Fistula.

In a short note on fecal fistula, in the *Canadian Practitioner*, March 1, 1889, Dr. James F. W. Ross, Surgeon to the Woman's Hospital in Toronto, says that within the last three months he has seen some curious occurrences in connection with operations inside the abdomen, which if not well authenticated by those engaged in this work all over the world, would be regarded as fabrications.

The idea of the terrible consequences of injuring the bowel during an operation now belongs to a bygone age. This accident was regarded as a very untoward one, but to his mind it has been proved that it is less dangerous to injure the bowel than to leave the source of illness behind. Unfinished operations in experienced hands have shown a large mortality. Operations a few years ago left unfinished from want of pluck, are to-day completed and the patient cured. He had seen, during the short space of three weeks, three cases of fecal fistula following abdominal section. In one case the ovaries and tubes were matted down after fourteen years of the old fashioned expectant treatment. It was hoped to relieve symptoms due to diseased ovaries, which were riddled with abscesses, by other means than those of operation. At last when the patient could not endure life longer in such a miserable condition, an operation was performed, before the difficulties of which hysterectomy pales into insignificance. A drainage tube was inserted, as there was much hemorrhage, and it was feared that during the separation of adhesions some damage might have been done to the bowel. The operation was brilliantly performed, and there are few men who could have carried it through to completion.

In twenty-four hours the patient was passing feces through the drainage tube, without the slightest inconvenience. In a few days the tube was taken out and the fistula began to contract. Enemata that were given washed out through the abdominal opening.

In the second case the patient was operated on for pyosalpinx, following a severe labor. The enucleation of the large adherent suppurating mass was very difficult and accompanied by severe hemorrhage. This patient also passed feces through the drainage tube, and made an excellent though rather tedious recovery. Her enemata also washed through the fistula.

The third case was one of supposed malignant disease, matting the small intestine and colon together in the left lower half of the abdomen. Nothing was done except to explore the mass. It was soft, felt as if malignant, and certainly could not be removed. The finger tore into it during examination. In this case a drainage tube was not used, but a fecal fistula resulted. Death was regarded as only a matter of time. The patient made a good recovery from the operation and the fecal fistula soon healed. The sequel shows the danger of giving an absolute opinion in such cases. The thickening disappeared and the operator concluded that the growth was not malignant. The moral from these cases is that fecal matter is not poisonous to the peritoneum, if it can readily escape. The old idea of the poisonous microbes in intestinal contents can hardly be worth consideration in the face of such clinical facts. No carbolic acid or any other disinfectant was used in any of these cases. Only cotton wool was used for a dressing. A glass tube, taken out of a card-board box, was inserted for a drainage tube. No turpentine and corrosive sublimate scrubbing of the abdominal walls was performed. Yet the instruments were clean, cleansed with soap and water; hands were clean, cleansed with soap and water; towels were clean, fresh from the laundry.

Any one who has passed his finger down the twenty-four hour old track of a glass drainage tube will have recognized its tube-like character. It is just like putting one's finger into a rubber tube. It is wonderful how nature effects such a channeling down to the pouch of Douglas, or any spot on which the drainage tube has rested. It is easy to understand how fæcal matter can readily be discharged into such a channel, while the rest of the peritoneum remains shut off by inflammatory, or at any rate by an adhesive, process.

Pathological Anatomy in Cases of Death after Extensive Burns.

In the *Deutsche med. Wochenschrift*, xv, 2, 1889, Dr. Eugen Fränkel asks how rapid death after extensive burns is to be explained? Ponfick has answered that death is the result of extensive disintegration of blood corpuscles and certain parenchymatous changes of the internal organs, which are the result of heat. Sonnenburg has cast doubt upon this opinion, but Fränkel is in a position to support it by investigations of the pathological anatomy. He found not only a large quantity of *débris* of blood corpuscles, but he could also demonstrate parenchymatous degenerations, especially in the liver and kidneys; and he thinks that the combination of degeneration of the secreting epithelium of the kidney with extensive obstruction of the uriniferous tubules by masses of hæmoglobin especially fatal. In one point Fränkel differs from Ponfick. He considers the parenchymatous degenerations not the result of disintegration of the blood corpuscles, but thinks that both the disintegration and the degeneration are effects of a poisonous product to be sought in the burns of the skin. How extraordinarily rapidly this poison acts may be judged from a case of Fränkel's, in which death occurred fifteen hours after the burn, and yet the autopsy showed marked conditions.—*Schmidt's Jahrbücher*, April, 1889.

Operation for Depressed Nipple.

Dr. W. L. Axford, of Chicago, says in the *Annals of Surgery*, April, 1889, that Mrs. H., a young German woman about three months advanced in her third pregnancy, was referred to him by Dr. F. B. Norcom, who wished to see if anything could be done for her badly retracted nipples. In her two preceding lactations she had not been able to nurse her children, though all known mechanical devices had been resorted to. The only relief for the woman was to suppress the milk as soon as possible. She was very anxious to nurse the expected child. Dr. Norcom said that some ten years ago he had succeeded in improving a depressed nipple by excising an elliptical piece of skin and drawing the edges of the wound together, and that, although the present case was much more unfavorable, he believed an operation feasible. The idea was entirely new to Dr. Axford.

On examination it was found that where there should have been a projecting nipple there was actually a depression into which the end of the little finger could be inserted. The breasts were perfectly healthy and otherwise well formed. The woman was a brunette, and the depressed nipple in its dark areola presented much the appearance of the invaginated finger of a dark brown kid glove. The right breast was deeper than the other.

Seizing the ends of the ducts with toothed forceps, the nipple could be easily drawn out to any reasonable extent. There were no adhesions or bands holding it down. An operation was proposed and accepted, and with the assistance of Drs. Norcom and Parsons, was done as follows: The right nipple was seized with the volsellum and drawn out till the skin was well on the stretch; beginning about one-third of an inch from the apex two curved incisions enclosing a crescent-shaped piece of skin were extended out in the breast for two and a half inches, and the skin and fat down to the fascia removed.

This area of denudation, Dr. Axford says, should have its greatest breadth at the base of the newly formed nipple. Three such excisions, radiating from the nipple were made. A catgut suture was now passed in and out, purse-string fashion, through the fascia, encircling the base of the nipple, and snugly tied at the point of entrance. This served to pucker up the fascia so that when the volsellum was removed the nipple showed no tendency to return to its inverted condition. This suture, he says, becomes completely buried when the denuded areas are closed. These areas were then closed with the continuous silk suture.

The result in the right and more depressed nipple was so satisfactory that it was decided to attempt an operation on the other. A similar operation was done, the lunes a little broader and the buried sutures a little deeper, with a much more satisfactory result. An antiseptic dressing was applied and the patient put to bed. The sutures were removed at the end of the seventh day, and the immediate result found to be excellent.

The anatomical construction of the breast, he states, furnishes the key to the operation. The fascia everywhere covering the surface of the gland protects the lactiferous ducts from injury, and when puckered up around the base of the well-drawn-out nipple forms a support for the soft yielding tissues of which it is composed, holding it out in its proper place. In both cases after tying the buried suture the nipples stood out without

the aid of the forceps. The closure of the lune-shaped areas in turn furnishes an additional support to that given by the puckered fascia, and adds to the projection of the nipple.

In conclusion, he calls attention to the fact that the field for this operation is limited, and states that it should be done only after the failure of mechanical devices fairly tried.

Iodol in Diseases of the Respiratory Organs.

In the *Canadian Practitioner*, March 1, 1889, there is a translation of an article by Dr. Dante Cervisato, of Padua, in which he says that the utility of iodine preparations in diseases of the respiratory organs has been disputed because it is feared that by their direct influence on the air passages, their bad influence on the digestive system, and their power of accelerating tissue change, instead of preventing the advance of the disease and promoting a cure, they may only hasten the course of the disease. In consideration of the many recently published successes in the treatment of diseases of the bronchi and lungs, particularly tuberculosis, by iodoform, he has, owing to the similarity of iodol to iodoform, used the former in the treatment of similar cases. The iodol was given internally in doses of 15 to 45 grains daily, and besides was applied locally in the form of inhalation, or insufflation to the larynx.

For inhalation, a watery alcoholic glycerine solution was used, in which very finely divided iodol was suspended.

In far advanced tuberculosis of the lung, with extensive cavities, no perceptible influence on the fever, cough, expectoration and general condition, could be observed. Cases of primary laryngeal tuberculosis were much improved both as to local condition and general symptoms. Sometimes apparently complete arrest of the process, and in many cases the transplanting of the disease in the lung, so long as the patient was under observation, prevented. Still he is not yet in the happy position of being able to publish cases of complete cure.

Great success attended the treatment of acute and chronic catarrh of the larynx by means of insufflation; especially in the acute and subacute forms rapid improvement was immediately noticeable. Iodol was very well borne even in cases where other kinds of treatment could not be carried on. In a case of extensive catarrh of the small bronchi (dry catarrh) with recurring fits of asthma, which occurred every ten to fifteen days, treated by iodol, internally and by inhalation, the catarrhal condition was much improved, cough much more seldom and easier, and the asthma did not recur during the two months the patient was under observation.

In two cases of dry bronchitis in children, one three, the other five, the internal administration of iodol caused increase of bronchial secretion and general improvement.

In three cases of stationary pleuritic exudation in children, pretty rapid resorption and final disappearance of the exudation was the result.

In some cases of chronic bronchial catarrh in children, in which the bronchial glands were supposed to be implicated, the general result was good, and particularly in two of the cases there was positive improvement of the general condition and bronchial symptoms, and disappearance of those symptoms supposed to be caused by the diseased glands.

Excessive Sensory Cortical Discharges and their Effects.

Dr. A. Hughes Bennett has a communication on this subject in the *Lancet*, March 30, and April 6, 1889. He uses the expression "cortical discharge" to mean a sudden liberation of the functional activity of any portion of the cortex cerebri. Excessive cortical discharge, he says, is consequent upon a state of hyper-excitability of the cellular elements of the brain caused by their irritation, which irritation may be induced either by mechanical, chemical, electrical, and other artificial agents, or by diseases of various kinds. This internal central change generates a corresponding series of external manifestations which take the form of explosions or sudden exaggerated paroxysms of that special function which is represented by the affected central gray matter. For example, if the motor area of the cortex be involved, a convulsion results; if the sensory region, a violent subjective storm of one or more senses. A "discharging lesion," therefore, is the state of instability of cortical cells, which in its turn may be due to a variety of pathological causes. The "discharge" itself is the sudden, excessive, concentrated liberation of their function, which as a consequence follows. The "symptoms of the discharge" are the paroxysmal exhibitions of excess of action of different kinds in different regions by those elements throughout the body

whose functions are represented in the centres which are involved by the disease.

Dr. Bennett has undertaken an investigation with a view to the localization of the special senses—sight, hearing, smell, taste, touch—using for this purpose the sensory symptoms which often precede and accompany an epileptic seizure. His experience is derived from a careful analysis of 500 consecutive cases of epilepsy and epileptiform attacks under his own care and investigated by himself. In few of these there was a *post-mortem* examination, but the symptoms observed speak for themselves. No exact statistical method, he says, is attempted, as those who deal with epilepsy will recognize the difficulty and uselessness attendant on such a method of investigation. In most instances the physician has to rely upon the statements of the patient or his friends, having rarely himself the opportunity of actually witnessing the seizure; but he states that in this inquiry every effort has been made, by the strictest cross-examination, to elucidate the facts. He was fortunate enough in a few but important exceptions to have actually been present at some of the attacks, and to have personally tested and confirmed the previous statements of the patient. As a matter of convenience he takes the consideration of the five special senses in the order of the frequency with which they are affected, namely: (1) touch; (2) sight; (3) hearing; (4) taste; and (5) smell.

The general conclusions which he derives from his investigation may be summarized as follows: 1. In a given series of cases of epilepsy or of epileptiform attacks there is a certain percentage in which a pronounced feature consists of an aura of one of the special senses. In 500 cases there was in round numbers an aura of the sense of touch in 10 per cent., of sight in 3 per cent., of hearing in 1.5 per cent., of smell in 0.75 per cent., and of taste in 0.75 per cent. 2. These auræ take the form of the development of crude subjective sensations of one of the special senses, and consist of a sudden attack of exaggerated sensation of pain, light, noise, smell, or taste. 3. These exaggerated sensations of sense are immediately succeeded by the opposite condition—namely, by a temporary abolition or diminution of the special sense previously affected, which results in anæsthesia, amblyopia, deafness, loss of taste, and anosmia. 4. These facts seem to indicate that each of the special senses is separately represented in the cerebral cortex, and that each of them is liable to disease. When by irritation they are in a hyper-physiological condition, they discharge their respective functions, the result being a crude subjective sensation of the corresponding sense. When destroyed or exhausted, the function is abolished or temporarily depressed. 5. The sensory cortical centres thus obey the same general laws, in their relations to disease, as do the motor cortical centres.

Sulphur in Chronic Diseases of the Alimentary Canal, Liver, Skin and Joints.

Sir Alfred B. Garrod, Consulting Physician to King's College Hospital, London, who is well known for his studies upon gout, communicates to the *Lancet*, April 6, 1889, an interesting paper on some chronic diseases of the alimentary canal, liver, skin and articulations, and their treatment by long-continued small doses of sulphur. Dr. Garrod states that sulphur influences the alimentary canal partly by a direct action upon its mucous membrane, partly by the circulation of sulphuretted hydrogen through the intestinal capillary system, and partly by the altered and increased flow of bile from the liver. A single lozenge taken at bedtime is sufficient to obviate the necessity for ordinary aperients. The lozenges he uses contain five grains of precipitated sulphur and one grain of cream of tartar. He finds them of great value in many morbid states of the alimentary canal and liver, as in cases of sluggishness of the liver and in piles; the bleeding in the latter condition is often completely stopped, and great relief of all the symptoms, especially of the accompanying pruritus, is obtained. The continued use of the lozenges is often quite effectual in overcoming habitual constipation without producing the unpleasant action often pertaining to ordinary aperient medicine.

In acne, psoriasis, and prurigo it is useful, either given alone or as an adjunct to other treatment. It is also useful in some of the localized forms of eczema, especially those connected with a gouty diathesis, as pruritus ani. Under the influence of small doses of sulphur when long continued, the complexion of the patient often improves to a marked degree.

Some arthritic diseases, especially chronic forms of rheumatoid arthritis and gout, and also many cases of muscular rheumatism, are much benefited by the treatment in question. The more chronic the disease

the more likely is sulphur to prove beneficial. In true gouty states of the joints, when the disease is both chronic and asthenic, sulphur is often a valuable adjunct to other remedies.

It will be seen from the foregoing that Dr. Garrod lays great stress upon the continued administration of the remedy, and the small dose. He is in the habit of giving one lozenge at bedtime for weeks, months, and in some cases years.

Recent Advances in the Treatment of Obstruction of the Nose.

At the recent meeting of the Harveian Society of London, Jan. 31, 1889, Dr. Scanes Spicer, after expressing his conviction that the importance of the nose in the economy is not yet sufficiently appreciated, made some preliminary remarks as to the recent proofs which have been afforded by physiologists that almost the whole of the warming, moistening, and filtering of the inspired air is done in the nose; and on the dangers and troubles which arise from the pernicious habit of mouth-breathing, a necessary consequent of chronic obstruction of the nose. He also referred to the frequently observed clinical association between abnormal conditions of the nasal fossæ and walls and many chronic functional derangements of the nervous system, such as depression, hypochondriasis, drowsiness, lassitude, inability to keep the attention fixed, as well as neuralgia, headache, paroxysmal sneezing, and asthma. He then passed critically in review the chief modern methods advocated for dealing with the various forms of obstruction of the nose. Among other points, he stated his preference for the galvano-cautery over chromic acid for inferior turbinated hypertrophies, because of the rapidity with which the former does its work without injury to the overlying ciliated epithelium (which it is so important to preserve), provided the platinum point is plunged into the hypertrophy and run along it under the mucous membrane. For middle turbinated hypertrophies he prefers chromic acid applied, on a platinum carrier and under a good illumination, to the exact spot to be reduced, his preference being based on the immediate shrinking properties of the acid on the tissues diminishing the risk of abnormal adhesions forming between adjacent parts. He specially insisted on the importance of systematic after-treatment of parts exposed by the removal of nasal polypi, to diminish or prevent the chance of their recurrence. He advocates for polypi the cold wire snare, and condemns the forceps as wanting in precision, painful, and dangerous. The necessity of removing the fetid adherent crusts which obstruct the upper channels and sinuses in ozæna before any real improvement could be expected was pointed out; for if not removed, the usual applications of douches, etc., never reach the diseased sinuses and cells. These can be kept clear only by systematic rhinoscopy and detachment, with delicate crocodile-mouth forceps, of tenacious crusts. The treatment of bony and cartilaginous outgrowths of the septum by the electro-motor trephine was described and the apparatus demonstrated. Trephining of these spurs was stated to be the most painless, the quickest, safest, cleanest, and most effectual way of removing them, so long the bugbear of rhinologists.

Cases were referred to in which deafness, tinnitus, loss of smell, insomnia, snoring, nasal voice, etc., speedily disappeared after the removal of obstructing spurs from the nostrils. In considering the treatment of post-nasal adenoid vegetations, the author said he always prefers when possible to clear out the growths at one operation by Löwenberg's forceps, the patient being anæsthetized. The paper concluded with a strong plea for a more general examination of the nose, and treatment of its morbid states by the numerous delicate, efficient, and satisfactory methods now available.

Mr. Frankish asked for the theory upon which was based the idea that nasal obstruction causes interference with nervous processes.

Dr. Hill commented upon the frequency of nasal obstruction in those suffering from sore throat. He has seen many operations performed upon the nose under the influence of cocaine, without much pain being experienced. He thought chromic acid of more use than Dr. Spicer was inclined to admit.

Dr. Spicer said that aprosexia resulted from a blockage of the communication which existed between the lymphatics of the dura mater and cranial cavity and those of the turbinated bones.—*British Med. Journal*, Feb. 9, 1889.

—Dr. George Johnson has been appointed one of the Physicians Extraordinary to Queen Victoria, in the room of the late Dr. C. J. B. Williams.

—It is reported that a family in London has been poisoned by the fumes from a number of green candles, which were found upon analysis to contain arsenic.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Physician's Daily Pocket Record, - - - 1.00
Reporter and Pocket Record, - - - - 6.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

TREATMENT OF PUERPERAL ENDOMETRITIS.

With the increase of knowledge concerning the nature and etiology of puerperal septic processes, and the methods of preventing infection, there has been a corresponding decrease in the percentage of cases of puerperal sepsis. This is especially true in well conducted hospitals. Whereas formerly the mortality from septic processes varied in maternity hospitals from three to twenty or more per cent., now, through the beneficent influence of antiseptic midwifery, the mortality from this cause is perhaps less than one per cent. And what is almost equally important, the percentage of morbidity has correspondingly decreased. Still, with the best of care, cases of sepsis do occur, and the practitioner must then face the problems of treatment rather than those of prophylaxis. Removal of particles of secudines, clots, and septic discharges, with the finger and disinfectant douche, together with the use of iodoform locally, and the administration of proper food and constitutional remedies are usually sufficient to arrest promptly the septic process and bring about a cure—especially in the hands of careful men who institute treatment early. But when cases are seen late and marked septic endometritis is present, or when the latter is present in spite of early treatment, the methods of treatment already mentioned are often ineffectual; salpingitis and peritonitis, or cellulitis and true pelvic abscess, or grave constitutional infection frequently follows, resulting in death, or more or less complete invalidism.

When septic endometritis occurs, the process of involution is arrested. The fatty metamorphosis in the layer of the decidua which remains attached to the uterus after labor is changed into a condition of necrosis. This layer of detritus and pus cells forms a favorable nidus for the multiplication of such microörganisms as have gained access to the cavity of the uterus, and thus favors infection of the muscularis and contiguous structures; in addition, the absorption of ptomaines, which result from the putrefaction of this material, causes grave constitutional poisoning. When the process has advanced so far as this, many obstetricians question the advisability of trusting to irrigation to remove this detritus, and assert, with apparent justice, that the irrigation removes only such matter as is free in the cavity of the uterus. They advocate, instead of repeated and continued douches, the thorough scraping of the uterus with the dull curette, whereby the necrosed decidua is thoroughly removed; and they declare that when the use of the curette is followed by a thorough irrigation, the cavity of the uterus is left in a relatively aseptic condi-

tion, and thus the course of the disease is much shortened and the necessity for repeated douching avoided.

Among others, Dr. Grandin, of New York, has recently advocated this method of treatment in a communication in the *New York Medical Journal*, Feby. 16, 1889. He states that as soon as fetor of the lochia appears he proceeds to find out its source. He considers that a thorough vaginal douche of boiled water or of some antiseptic solution will cause this fetor to disappear, if it be due to decomposition of the lochia or a clot in the vagina. Should the fetor reappear after the lapse of a few hours, an intra-uterine douche is administered, as the cause may be the retention *in utero* of a clot or of loosened *débris*. If, notwithstanding this douche, the fetor reappears Dr. Grandin believes that the time for active treatment has come. The position of the uterus is determined by bi-manual examination, the patient is put in Sims's position, a tenaculum is hooked into the anterior lip of the cervix to steady the uterus, and a properly curved curette is inserted into the uterine cavity. Then the entire endometrium is thoroughly scraped. In this way Dr. Grandin says that he has literally removed handfuls of degenerated *débris*. When the curetting is done the patient is turned on her back and the uterus thoroughly washed out. Dr. Grandin asserts further that in his experience it has never been necessary to repeat the curetting, and rarely has an additional douching been called for. He moreover affirms that in certain aggravated cases of septic endometritis which he has seen, in which the fetor was intense, the pulse rapid, and the aspect bad, there has been such a marked improvement within twenty-four hours after the removal of the putrid products that it was difficult to realize that he was dealing with the same patient.

There are fashions in medicine as well as in dress, and just now it is becoming the fashion to advocate the use of the curette in cases of septic endometritis after labor. The method of treatment outlined in the first part of this article has been thoroughly tested, and when it has been instituted early the result usually has been good. Hence we believe that the cases are exceptional in which the use of the curette is necessary—those in which the usual treatment has proved ineffectual, and those seen late. In these proper cases, we believe that the use of the curette is clearly indicated, and that it will yield prompt results, especially when the exploring finger is also employed to determine that the uterine cavity is thoroughly emptied. An indication for the employment of the utmost care is the co-existence of parametritis, salpingitis or peritonitis; and interference is positively contra-indicated unless it be certain that a centre of infection is located within the cavity of the uterus.

THE HOUR OF DEATH.

There is a wide-spread popular impression that a very large proportion of deaths from disease take place in the early morning hours—between four and six o'clock. That this is an error is well known to most medical men. From time to time careful observations have been made in hospitals which have resulted in showing that the act of death takes place with fairly equal frequency during the whole twenty-four hours of the day.

Very recently, as reported in the *Journal de Médecine* of Paris, March 24, 1889, an investigation has been made, which showed that there was a certain falling off of the number of deaths between seven and eleven o'clock in the evening, but that, with this exception, the proportion of deaths is about even.

We refer to the matter because some of our readers may be glad to have authority for correcting a misapprehension which is of no very great importance, it is true, but which is held with great tenacity by persons who are hard to convince of error.

THE RESULT OF PASTEUR'S TREATMENT OF HYDROPHOBIA.

The effect of the attention attracted to hydrophobia in France and certain other parts of Europe by the discussion and practice of Pasteur's method of treating persons bitten by animals supposed to be rabid, has been to increase the mortality from what is called hydrophobia. In France the number of deaths has increased so much since this "infallible" method has been in use that in the Department of the Seine—which includes Paris, the centre of Pasteur's operations—there were nineteen deaths attributed to hydrophobia last year. The partisans of Pasteur's method ingeniously manipulate the statistics, so as to make it appear that this is not due to any defect in the method, but they appear to be blind to the obvious inference to be drawn from the fact that in France hydrophobia seems to be on the increase, while in Germany, where Pasteur's methods have never been approved or adopted, hydrophobia has almost utterly disappeared.

Another interesting point in regard to this matter is the fact that Pasteur several years ago announced that he had discovered a method by which dogs, to any number, could be rendered "refractory" to rabies, and yet there is no evidence that he has ever applied this merciful discovery; so that in France dogs "go mad" as much as ever, and all the energy of Pasteur and his followers is directed toward a malady which would be unknown if his method for dogs were really trustworthy and if it were put in practice as it ought to be. Meanwhile good laws for the management of dogs, and good sense on the part of medical men, have reduced rabies almost to an unknown quantity in Germany.

The facts indicate the danger of following an *ignis fatuus*, and may support the conviction of Americans who have never consented to importing into this country a theory and a practice which has worked so poorly in France.

AMERICAN PUBLIC HEALTH ASSOCIATION.—The American Public Health Association will hold its seventeenth annual meeting at Brooklyn, N. Y., Tuesday, Wednesday, Thursday and Friday, October 22–25, 1889. A preliminary announcement, containing a list of the topics for consideration at the meeting, has been issued by the Secretary, Dr. Irving A. Watson, of Concord, N. H.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

A MANUAL OF INSTRUCTION IN THE PRINCIPLES OF PROMPT AID TO THE INJURED. DESIGNED FOR MILITARY AND CIVIL USE. By ALVAH H. DOTY, M.D., Major and Surgeon, Ninth Regiment, N. G. S. N. Y., etc. Small 8vo, pp. xiii, 224. New York: D. Appleton and Company, 1889. Price, $1.25.

This book contains a great deal of valuable instruction in regard to the management of a variety of accidents and emergencies, and is very abundantly and handsomely illustrated. From our point of view it contains also a great deal which has no special bearing on the subject. The sixty-seven pages devoted to anatomy and physiology are interesting, but, in our opinion rather an encumbrance to a book apparently intended for the laity. If the book is meant for the instruction of hospital stewards, in the army, this will probably be no objection to it.

The general teaching of the book is excellent; but we regret to see the old and widespread error in regard to the treatment of frozen persons repeated and endorsed by the author, and also that the "triangular bandage" of Esmarch is spoken of in a way which shows no knowledge of the fact that it is but a part of the admirable "handkerchief system" of M. Mayor, which has been before the profession for fifty years.

TREATISE ON DISEASES OF THE TESTICLE AND ITS ADNEXA. TRAITÉ DES MALADIES DU TESTICULE ET DE SES ANNEXES, par CH. MONOD, professeur agrégé à la Faculté de médecine de Paris, chirurgien de l'hôpital Saint-Antoine, etc., et O. TERRILLON, professeur agrégé à la Faculté de médecine de Paris, chirurgien de la Salpêtrière, etc. 1 vol. in-8° avec 92 fig. dans le texte. 16 fr.

8vo, pp. xi, 806, with 92 illustrations. Paris: G. Masson, 1889. Price, 16 francs.

This is a magnificent book, on a subject which has not been so fully discussed by any author before Drs. Monod and Terrillon took it up. They have gone at it with a thoroughness, and have concluded it with a finish, which would hardly be possible in any country outside of France. The result is a work which will be classic, a work in which large acquaintance with the subject in hand, great clearness of style, and abundance of admirable illustrations combine to make a book indispensable to the specialist in genito-urinary surgery and of great value to every studious surgeon. We can heartily recommend it to the attention of those of our readers who read the French language, and regret that more of them cannot do so.

In preparing the book before us, the publisher has ably seconded the endeavor of the authors to make it a credit to the country from which it comes.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

280. Diseases of the Skin Associated with Disorders of the Female Sexual Organs. By George H. Rohé, M.D., Baltimore. From the *Buffalo Med. and Surg. Journal*, February, 1889. 13 pages.

281. Second Annual Report of the Ophthalmological Department of the State Hospital at Norristown, Pa., for the Year 1887. By Charles A. Oliver, M.D., Philadelphia. 7 pages.

282. Discussion on the New Cæsarean Section. By Howard A. Kelly, M.D., Philadelphia. From the *Transactions of the American Gynæcological Society*, 1888. 8 pages.

283. Examination of the Ureters. By Howard A. Kelly, Philadelphia. From the *Transactions of the Amer. Gynæcological Society*, 1888. 14 pages.

284. Contributions to the History of Development of the Teeth. By Carl Heitzmann, M.D., and C. F. W. Bödecker, D.D.S., New York. From the *Independent Practitioner*, vols. viii and ix. 98 pages.

285. Chronic Interstitial Nephritis, etc. By James Tyson, M.D., Philadelphia. From the *University Medical Magazine.* 8 pages.

286. Epidemic Cerebro-Spinal Meningitis. By James Tyson, M.D., Philadelphia. From the *Philadelphia Medical Times*, Nov. 15, 1888. 12 pages.

287. The Relation of Albuminuria to Life Assurance. By James Tyson, M.D., Philadelphia. From the *Medical News*, November 17, 1888. 14 pages.

288. Some General Remarks on Blood-letting. By G. Maxwell Christine, M.D., Philadelphia. 12 pages.

280. Dr. Rohé, in this paper, has collated a number of cases in which various skin-diseases have been observed associated with diseases of the sexual organs of women, as well as with certain physiological processes like lactation. It is an interesting and suggestive pamphlet.

281. This pamphlet is one of the indices of the careful work which is done in studying the condition of the insane at the Norristown Hospital. The conclusions of Dr. Oliver are valuable in filling out an obscure part of a picture which still lacks much of being complete.

282. Dr. Kelly, in this pamphlet, describes briefly two cases in which he performed Cæsarean section successfully, and the details of the method which modern experience has shown to be most calculated to secure a good result.

283. In this paper Dr. Kelly describes the methods of examining the ureters in women by means of the catheter and by palpation. These open up a wide field of investigation to the gynecologist, and ought to be understood by all surgeons. As described by Dr. Kelly they are not very difficult to carry out, and they are capable of affording very useful information in the treatment of certain diseases of women.

284. The monograph of Drs. Heitzmann and Bödecker contains an exceedingly interesting and thorough study of the histology of the teeth during the period of development. It is illustrated by a large number of admirable engravings of the microscopic appearance of sections of fetal teeth and of their surrounding parts. As a whole the paper is an unusually valuable contribution to the literature of the subject, and might well be in the hands of all intelligent dentists as well as all physicians interested in the fascinating theme of which it treats.

285. Dr. Tyson's paper contains a careful study of the histology of the chronically contracted kidney, in which he supports the theory that thickening of the walls of the arterioles in the kidney, and elsewhere in the body, is an important and perhaps constant factor of the disease. He dissents from the views expressed by Dr. Arthur Meigs, in his paper noticed in these columns Nov. 10, 1888 (Pamphlet notice No. 145). His paper contains, also, an interesting statement of the treatment proper for cases of chronic contracted kidney.

286. This is a clinical lecture by Dr. Tyson, delivered at the Philadelphia Hospital last November, and discusses the symptoms, morbid anatomy, and treatment of cerebro-spinal meningitis.

287. In this paper, which was read before the *Association of American Physicians* last year, Dr. Tyson opposes, with the authority of his long study and large experience in diseases of the kidneys, the view that mere albuminuria should be regarded as an insurmountable bar to life insurance, and gives the points which ought to be considered by medical examiners before accepting or rejecting an applicant who at times has albumin in his urine.

288. "Saul is found among the prophets" so often nowadays, that it excites little surprise to find a homœopathic physician, like Dr. Christine, advocating the practice of such an un-homœopathic procedure as blood-letting, and defending his course theoretically by quotations from homœopathic writers, while demonstrating its soundness by quoting from the most orthodox of the old school. The whole of the practical part of this interesting paper is founded upon citations from Wyeth, Agnew, Quain's Dictionary, and Sir Thomas Watson, and the experience of the author, who has learned that the homœopathic law is not one of universal applicability.

—For the effectual protection of woolen goods against moths the use of cedar-wood boxes and closets is insufficient, and it is stated that there is no other means of protection against the ravages of the insect but perfectly to inclose the woolens in material which is not attacked by the moth, such as cotton cloth. Woolen goods brushed clean from dust, folded together and put into cotton bags, which were well tied, have been found perfectly intact when taken out at the change of the season. The important point, of course, is to see that the clothing is free from moths when first put away.

CORRESPONDENCE.

Congenital Absence of Fingers.

TO THE EDITOR.

Sir: I was called May 8, 1889, to Mrs. X., in labor with her third child. The labor was normal, and the child weighed eight pounds and was well developed, except the left hand, in which development was arrested at the carpal and metacarpal articulation. The stump was soft and there was no cicatrix. There were five small tubercles on the end of the stump, corresponding with the fingers and thumb from ulna to radius. The smallest tubercle, on the ulner side, was about the size of a bird-shot; the largest, on the radial side, was about the size of a small pea. The carpus can be flexed and extended; the radius and ulna are of the same length as the bones in the right arm.

If you think this case of sufficient interest to be placed on record, please give it space in the MEDICAL AND SURGICAL REPORTER.

Yours truly,

ORSON HOUGH, M.D.

Conneautville, Pa.,
May 29, 1889.

Midwives in West Virginia.

TO THE EDITOR.

Sir: As the MEDICAL AND SURGICAL REPORTER is taken by many of the physicians of my State—West Virginia—I wish to take up a small amount of your space, and write on the subject of "Midwives," or, I should say, those pretending to be such. Since living in this State, I have found to my surprise that the laws are peculiar here, in regard to the practice of midwifery. I am told that these women, often without any education and with little practical sense, may, according to the laws of the State, practise without a license, or certificate, or any examination whatever. A midwife may register at the Clerk's Office, but is not compelled to do so.

Is not child-birth of more importance than that? Does not this belong to the practice of medicine as much as giving powders and looking at tongues? I cannot understand how any State can be so careful that the young physician should have his diploma from the best schools of our land, and see that he has a State certificate to practise his profession, while it permits any woman, who wishes to do so, to practise midwifery. The result of this plan is, that the practice of educated physicians is interfered with, while the lives of women are sacrificed to the ignorance of their attendants. This I find is the observation of my fellow-practitioners, as well as mine; and I call attention to it, in the hope that a more sensible way may be adopted by the authorities of this State.

Yours truly,

MEDICUS.

May 22, 1888.

NOTES AND COMMENTS.

Condition of Physicians in Johnstown.

Dr. C. K. Mills and Dr. Thomas Mays arrived at Johnstown on June 10th, representing the joint committee of the College of Physicians of Philadelphia and the Philadelphia County Medical Society, to bring relief to medical practitioners and their families suffering from the flood. Six physicians were drowned and 21 lost all they had. The number to be cared for is about 20. It is said that about $2000 will be immediately expended in the work, more money being ready to continue it.

The Pennsylvania Medical Society and the Sufferers by the Flood.

The Pennsylvania Medical Society which convened in Pittsburgh on Tuesday, June 4, after passing appropriate resolutions of sympathy with our brethren and the families of those who are lost in the recent floods in Pennsylvania appropriated $1000 for their relief, and adjourned to September 3d. All County Societies were urged to take immediate steps to render aid through the Cambria County Medical Society, of which Dr. F. Shill, of Johnstown, is Treasurer.

Philadelphia Medical Societies and the Sufferers from the Flood.

At a special meeting of the Philadelphia County Medical Society, held June 6, 1889, the following Minute and Resolutions were unanimously adopted:—The members of the Philadelphia County Medical Society, in common with their fellow men and women of all pursuits, have been deeply moved by the loss of life and suffering caused by the recent terrible floods; especially at Johnstown and other places in the Conemaugh Valley. As individual men and women they have felt it their duty to contribute, with the rest of the community and to the very

best of their ability, to one or other of the funds collected under various auspices and intended to be disbursed by the Citizens' Committee, for the relief of suffering men and women without distinction. But as an association of physicians, we have felt that our duty did not end here. Realizing as we do the hardships and struggles, and, at best, limited pecuniary rewards of the practice of the profession peculiarly devoted to the relief of human suffering, and having learned that the surviving members of that profession residing in the flooded districts have lost everything they possessed—some of them thus left destitute in old age, after years of faithful endeavor; we feel an additional responsibility resting upon us for the assistance of these, our brethren; that they may be enabled as soon as possible to resume the laborious duties of the practice of the sacred profession of medicine.

This meeting is therefore called to give practical expression to our sympathy with the physicians of the storm-stricken region; and to devise a plan whereby this Society in conjunction with other medical associations of this city, of the state, and of the United States, may collect and wisely disburse, after conference with the general committee and with our distressed colleagues, an amount of money commensurate with the responsibilities of the occasion and adequate to its needs.

Resolved, that the Philadelphia County Medical Society sends its earnest sympathy to the physicians of Johnstown and other flooded places, and pledges itself to aid them to the extent of its ability.

Resolved that a committee of three be appointed to act with the committee of the College of Physicians and with committees that may be appointed for the same purpose by other medical organizations of the city, state, and country, to collect funds for the assistance of physicians and their families, and to disburse same in such manner as may be deemed most advisable after conference with the physicians of the flooded districts and with the general relief committee.

Resolved that the committees of this Society and of the College of Physicians be requested to meet at once and to report to this meeting a list of two or more physicians in each ward of this city, to act as subcommittees for the collection of funds from physicians in their respective districts.

The following Committee was then appointed to act for the Philadelphia County Medical Society: Drs. T. J. Mays, H. Augustus Wilson and S. Solis-Cohen. The Committee of the College of Physicians consists of Dr. J. Ewing Mears, Charles K. Mills, and Harrison Allen.

The Sanitary Conditions at Johnstown.

Dr. John B. Hamilton, Surgeon General of the Marine Hospital Service, has made a report to the President in regard to the situation of affairs at Johnstown, Pa.

Dr. Hamilton says that the work of clearing up the surface débris was going on well, and, in his judgment, ten days more of the same systematic work would suffice to clear the surface of the main portion of the late city. "The sick and wounded are now mainly confined to those persons working as laborers, and in the various relief organizations outside of the laborers there are few citizens left. Many are lost and many are gone away from the scene of their great calamity. There are some twenty physicians, ten of whom are able to work, but no more are needed, and it would be a great relief if many of those from a distance would go away.

"The water supply of Johnstown is from Stony creek, some miles above the scene of disaster, and is pure, wholesome water. There is little danger of an epidemic among the inhabitants of Johnstown. The danger point, from a sanitary point of view, is the drift at the bridge, and this danger is not to the inhabitants of Johnstown, but to those people depending on the lower river for their water supply. This water, if boiled before drinking, will not be unhealthy, but the thought of drinking water contaminated by dead bodies of human beings and animals is revolting."

The report is confined to the portion covered by Johnstown proper. No attempt has been made to touch upon the general condition of the outlying villages which also suffered from the calamity.

Dr. Groff, a member of the State Board of Health, in charge of the Sanitary Corps, issued the following bulletin on June 10: "The favorable condition stated in the first report continues. No contagious disease of any kind prevails. There are a few cases of a mild type of measles. No signs of any epidemic are manifest. The State Board of Health is fully prepared to meet all emergencies as they arise. As a precautionary measure a hospital for contagious diseases has been established, and if any cases appear they will be promptly met. The air continues pure and wholesome, the water pure. The bodies still in the wreck are so covered

with earth as not to be dangerous to health. There is every precaution being taken to prevent contamination of the water supply for the towns below Johnstown. There is no ground whatever for alarm in this matter at present. The bodies in the river are covered with mud and earth, so as not to be dangerous to health. The weather is cool and most favorable. Though the destruction of life has been appalling, there is at present every reason to be encouraged."

Case of Poisoning with Antifebrin.

Dr. E. Fürth communicates an account of a case of poisoning with antifebrin to the *Wiener med. Presse*, April 21, 1889. A girl suffering with violent hemicrania took sixty grains of antifebrin. Shortly after taking it nausea, eructations and a tendency to vomit occurred. Milk was given her as an antidote by the by-standers, but was immediately vomited. When Dr. Fürth saw the patient, about two hours after the poisoning, he found her deeply unconscious, emitting repeatedly cries of pain and complaining loudly of pains in the epigastrium. The face, with exception of the lips, which were somewhat cyanotic, was deadly pale. The skin felt icy cold; the pulse was 140, weak, scarcely to be felt; respiration was superficial and somewhat quickened. Stimulants were vomited, as the milk had been. Altogether the patient vomited fifteen times, a greenish-watery fluid. One hour later cyanosis spread to the face, so that four hours after the antifebrin was taken the face was reddish blue. The hands also and the feet were deeply cyanosed, especially the fingers; the rest of the body remained pale. In addition there were symptoms of brain irritation: dilated pupils, spasms of the face, gnashing of the teeth, immobility of the upper and lower extremities, lively delirium, which lasted only a short time but was repeated many times. The patient then sank into deep coma, from which she only gradually aroused after the lapse of three hours.

Eight hours after the poisoning, the patient had become again entirely conscious and complained simply of pain in the stomach and of a feeling of dizziness. The pulse was 84, moderately strong; respiration quiet; temperature somewhat below normal. The cyanosis disappeared first after the lapse of twenty-four hours, fading first from the extremities and last from the lips. The patient was able to leave bed in two days.

Sanitary Condition of Paris.

Now that the Paris Exposition is attracting a great crowd of strangers to Paris, it is not without interest to note the excellent sanitary condition of that city. The mortality has at no time this year reached so small a figure as in the week ending May 4. The average for this week in the past five years has been 1,122. This year the mortality was only 984; and in the week following, it fell to 951. Typhoid fever especially has shown, since 1888, a constant decrease. More than all others, this affection belongs to the list of diseases which may be avoided; and it is only necessary that there should be due energy on the part of the public authorities to reduce its frequency in a notable proportion. While typhoid fever and varioloid have decreased, it is unfortunate to note that this is not true of measles and of diphtheria. This results, no doubt, from the fact that the measures which can stay the progress of these diseases depend more upon individual initiative than on public measures. Among the causes which may explain the improved health of Paris may be noted the increased use of the conveyances which are placed by the police at the disposal of those wishing to transport persons suspected of being affected with contagious diseases. In 1886 these carriages were called for only at the rate of thirty to forty per month. In 1888, in the month of April, this number had increased to 211; and in the April just passed, to 231. Another cause acting beneficially is doubtless the improvement in the quality of milk—an improvement due to the constant control exercised by the city laboratory.—*Science*, May 31, 1889.

Immediate Relief of Hoarseness.

The first Napoleon is said to have been subject to sudden attacks of severe hoarseness, for the immediate relief of which his physician was in the habit of prescribing the following, known as Foreau's syrup:

℞ Liquor. Ammoniæ fortioris . ♏x
Syrupi Erysemi . . . . . f℥iss
Infusionis Tiliæ Florum . . . f℥iiss
M. To be taken at one dose.

Erysemum officinale (*sisymbrium offic.*) or hedge-mustard is no longer official, but is easily obtained. It is a small annual, growing almost everywhere in the United States and Canada, as well as in Europe. The infusion of linden (tilia) is used simply as an agreeable vehicle, and may be dispensed with or supplanted by any other pleasant vehicle.—*St. Louis Med. and Surg. Journal*, May, 1889.

Simulo as a Remedy in Epilepsy.

Dr. M. Allen Starr, Clinical Professor of Diseases of the Mind and Nervous System in the College of Physicians and Surgeons, New York City, has a communication on Simulo as a Remedy in Epilepsy in the New York *Medical Record*, May 11, 1889. He reports seven cases in which it was used and concludes that simulo has no effect upon attacks of hystero-epilepsy or upon the hysterical state. It has also no effect in modifying the frequency or severity of attacks of *petit mal*, or of procursive epilepsy. It has some effect in modifying the frequency and severity of attacks of *grand mal*, but is inferior in this respect to the bromides. In cases in which for any reason it is deemed necessary to suspend the bromides, he says it would be well to substitute simulo for them.

There seem to be no ill effects from the use of the drug. He found no evidence of change in the rate or character of the pulse or respiration, no dilatation or contraction of the pupils, no muscular weakness, no mental depression or excitement, and no disturbance of the digestion in the doses in which it was used. The suggestion made by Eulenburg, that it would be well to obtain the active principle of the drug, is worthy of consideration. And Dr. Starr thinks it would be well to increase the dose progressively until one or even two ounces are used daily. The chief objection to its use at present is its costliness, the price being twenty-five cents an ounce.

The preparation used by Dr. Starr was the tincture, which is of a yellowish-brown color, and has an aromatic taste, reminding one slightly of sherry. The usual dose was two fluid drachms, three times a day.

Danger of the Suspension Treatment of Locomotor Ataxia.

Dr. Vincent, of Clifton Springs Sanitarium, recently hanged himself unintentionally while experimenting with the Sayre suspension apparatus, which many physicians are now making trial of in the treatment of locomotor ataxia. This unfortunate accident is not the only one, for word comes from France that a man living in the Department of the Dordogne, who was suffering with locomotor ataxia, met his death in the same way. Both these deaths occurred while the persons were alone. The apparatus appears to be free from danger when it is employed under the watchful eye of the physician or in the presence of a skillful attendant.

The New Quarantine Station at the Entrance to Delaware Bay.

It will be remembered that Congress at its last session appropriated a considerable amount of money for the equipment of seven quarantine stations, five for the Atlantic Coast and two for the Pacific. Of this appropriation about $75,000 was assigned for the establishment of a thoroughly-equipped station for the protection of the Delaware Bay and River. Heretofore the only safeguard against the introduction of contagion below the Lazaretto has been the little Hospital of the United States Marine Hospital Service, near Lewes, which was designed simply for the treatment of sick or wounded seamen, with no adequate provision for the isolation of those suffering from infectious diseases. So well has this service been administered, however, that it has on several occasions detained and disinfected pest-laden vessels and their crews, and thus stayed at the threshold diseases which might have led to disastrous epidemics had they gained admission. At or near this point, the Legislature of Delaware has offered to cede to the United States the land necessary for the proposed buildings and appurtenances. The Secretary of the State Board of Health of Pennsylvania, Dr. Benjamin Lee, has been designated a Commissioner on the part of the United States to meet Commissioners appointed by the State of Delaware, and, in conjunction with them to locate and fix the boundaries of this grant. This preliminary will be speedily settled, and work will be begun on the station at an early date. The fumigating steamer for the station is now in process of construction, at Wilmington, Delaware.

A Hospital for Dartmouth.

Mr. Hiram Hitchcock has given to Dartmouth College a hospital, which is to be attached to the Medical School of that institution. The plans for the new building are still in the hands of the architect, but it is expected that the structure will be completed within a year. The ground has been purchased in Hanover, and everything is now in readiness to proceed with the work as soon as the plans shall have been approved. Mr. Hitchcock was led to make this gift by an appreciation of its necessity and by a desire to establish a fitting memorial to his late wife. It will be the handsomest and best equipped institution of the kind in Northern New England.—*Medical Record*, June 8, 1889.

Over-pressure in Schools.

Dr. James Simpson, President of the California State Medical Society, in his annual address before the Society, in April, 1889, speaks as follows concerning over-pressure in schools (*Occidental Medical Times*, May, 1889):

"A diligent search, from the physician's standpoint, into the workings of the modern educational system has led me to regard it with trust and admiration, and has taught me that much of the cry about over-pressure is pure sensationalism. Those who repeat that cry are perhaps sincere, but they often do so without a practical knowledge of the subject, stirred by the hasty fervor that seizes us when we discover a wrong that wants righting. The public look to us for carefully balanced and sifted statements on these questions of general import, and it is regrettable that physicians who have been held up as authorities have solemnly warned them that, in such healthful exercise of the mental cortex of our youth as is provided in school discipline, danger and destruction lurk. Let us be sure we are right before sounding the note of alarm. With the pleasing methods of teaching now in vogue, with the ever-advancing observance of the laws of cerebral hygiene, and with the better provisions for the health and comfort of scholars, most children are better situated in the school-room than at home. Let the contrast be made, as it often must be, between the clean, pleasant class-room on the one hand, and the foul atmosphere, actual or moral, of an ill-kept home on the other. The school-house of to-day, conducted by the teacher of to-day, is the best possible nursing place for strong, broad-minded, intelligent American citizens."

Antiseptic Power of Salol.

At the meeting of the Hunterian Society of London, April 10, Mr. Corner introduced a series of cases illustrative of the antiseptic power of salol (salicylate of phenol) as a dressing for wounds, after the part had been rendered aseptic by a 1 in 20 solution of carbolic acid. He did not claim for it greater power than iodoform, and probably other antiseptics have, but he says it has advantages over some. It possesses a pleasant aromatic odor, can be used freely without fear of irritation or poisoning, is absorbent of moisture, which drying forms a hard but friable covering. It will prevent putrefaction; it will not destroy it when once established. It has been used in increasing frequency for several years at the Poplar Hospital, and with excellent results, in compound fractures and dislocations, also as a dressing in amputations, minor and major, and in compound comminuted and depressed fractures of the skull. The first case shown by Dr. Corner was a compound comminuted depressed fracture of the frontal bone, in which the bone was elevated and some spicules removed. Afterward the wound was washed with a solution of carbolic acid (1 in 20), the opening filled with salol, and a drainage-tube inserted. The dressing was undisturbed for fourteen days, remained sweet, and healed on the twenty-sixth day. His temperature remained from the first under 100°. A second case, treated in January, 1889, was a compound fracture of the olecranon, head of radius, and humerus, opening the elbow-joint, with considerable damage to the soft parts, the elbow having been crushed by the passage of a railway engine over it. The olecranon was splintered and drawn up, causing serious tension of the skin and necessitating removal of both portions. The antiseptic treatment and dressing were the same as in the previous case, but required changing after four hours and again next day, in consequence of oozing of secretions through the dressing. The parts were then left untouched for thirty days. The temperature went up the day after the injury, and remained about 101° for three days, 100° for two days, and then fell to normal. Two other cases were shown: one a crushed compound fractured finger, dressed twenty-one days before, and not exposed since, there having been neither pain nor elevation of temperature; the other was a compound fracture of the first phalanx of the finger, only dressed at the time of the accident, and left undisturbed for a month, when it was found perfectly healed. Dr. Corner pointed out that this was the common experience in such cases, and that even if gangrene followed the parts remained sweet. —*Lancet*, May 4, 1889.

Cotton Impregnated with Biniodide of Mercury.

The following formula is given in several foreign journals for the preparation of antiseptic cotton:

Biniodide of mercury .	8 parts;
Iodide of potassium . .	3 "
Glycerin	120 "
Distilled water . . .	to 2,400 "

Absorbent cotton is to be soaked in the solution and then dried.

NEWS.

—Mrs. Jane C. Stormont, the widow of Dr. D. W. Stormont, has given $10,000 to the Kansas Medical Society.

—The American International Congress of Medical Jurisprudence held its first meeting in New York City, June 4.

—On June 4, 1889, the trustees of the University of Pennsylvania elected Dr. John H. Musser Assistant Professor of Clinical Medicine.

—Dr. George H. Makuen, of the staff of Cooper Hospital, Camden, has been appointed Assistant Demonstrator of Anatomy in the Jefferson Medical College.

—It is reported that the City Council of Newport, Rhode Island, has appropriated $300 for the entertainment of the American Medical Association, at its meeting there this month.

—Dr. A. B. Ashworth, the business manager of the *Atlanta Med. and Surg. Journal*, died suddenly in Atlanta on May 18. Dr. Ashworth was graduated from the Atlanta Medical College in 1886.

—At the fortieth annual meeting of the Medical Society of Northampton County, a dinner will be given in honor of Dr. Traill Green, of Easton, Pa., at the Paxinosa Inn, Thursday evening, June 20.

—Dr. Roswell Park, of Buffalo, has been invited to deliver the Mütter lectures on "Some Point or Points connected with Surgical Pathology," before the College of Physicians of Philadelphia, during the winter of 1890–91.

—The grand jury in New York has found indictments for violation of the sanitary law against Doctors Irwin, Ferguson and Hance, the physicians who performed the autopsy on the body of Washington Irving Bishop, the mind reader.

—The Warren Triennial Prize of the Massachusetts General Hospital, amounting to $500, has been awarded to Dr. H. A. Hare and Dr. Edward Martin, of Philadelphia, for an essay on "Some New Studies on the Phrenic Nerve and Artificial Respiration."

—The *American Lancet*, June, 1889, says: The medical profession of Michigan are almost unanimous in the desire that the Medical Department of the Michigan University should be removed to Detroit. But they are not unanimous as to the means by which this end can be accomplished. The most important obstacle is the lack of about a half a million of dollars with which to erect and put in order a plant for its use in Detroit. Possibly a couple hundred thousand dollars less might accomplish the end, but an additional quarter of a million would be far better.

HUMOR.

FOGG SAYS that some of the people on the theatrical stage remind him of his liver, because they don't act worth a cent.—*Boston Transcript.*

A SOUTHERN HOTEL advertises among its attractions a "parlor for ladies 35 feet wide." We trust this paragraph will catch the eye of the woman who occupies three seats in a crowded car.—*Yonkers Statesman.*

A PROFESSIONAL FAILURE.—"Can you recommend something as a spring tonic?" inquired a sallow dyspeptic, stepping listlessly into an aromatic pharmacy. "Yes," replied the druggist, "I have a number of excellent preparations. What is your line of business?" "I am a professional Faith Curer."—*The Epoch.*

A REMARKABLE CHILD.—Caller (*to fond mother*).—"Isn't it somewhat remarkable and wonderful, Mrs. Hobson, that your little boy Frank, though eight years old, can neither read nor write?" Fond Mother.—"Oh yes, I think so. The dear little fellow always was a remarkable and wonderful child."—*Harper's Magazine.*

DIVIDING THE RESPONSIBILITY.—Doctor—"Yes, you have a tremendous fever. Burning thirst, I suppose?" Patient—"Yes, terrific." Doctor—"Ah, I'll send you round something to relieve that." Patient—"Never mind about the thirst, Doctor. You look after the fever; I'll attend to the thirst myself."—*London Pick-Me-Up.*

OBITUARY.

SAMUEL G. LANE, M.D.

Dr. Samuel G. Lane, a well-known physician of Chambersburg, Pennsylvania, died there June 4, of apoplexy, after a brief illness. Dr. Lane was 62 years old, and was graduated from the Medical Department of the University of Pennsylvania in 1849. He was a member of the Local Board of Pension Examiners, and a trustee of the Pennsylvania State Hospital for the Insane. He was a writer of much ability, and was a frequent contributor to the medical and historical journals.

WHOLESALE AGENTS,

No. 815 FILBERT STREET,

PHILADELPHIA.

McARTHUR'S SYRUP.

(SYR : HYPOPHOS : COMP : C. P. McARTHUR.)

Its use is indicated in Consumption and Tuberculosis, Diseases of the Chest, Chronic Cough, Throat Affections, General Debility, Brain Exhaustion, Impotence and Loss of Memory.

The point of primary importance in the use of the Hypophosphites is their *chemical* purity, but unfortunately they are too often adulterated.

So little seems to be generally known, even among the medical profession, with regard to the chemistry of the Hypophosphites, and the absolute necessity of CHEMICAL purity, that we call attention to this point.

One of the first effects produced by the use of our CHEMICALLY PURE Hypophosphites is a general increase of nervous energy, with a feeling of ease and comfort.

The second effect is an increase of appetite; digestion is improved, and the bowels become regular in their action, the quantity and color of the blood is increased, respiration is controlled, a better expansion of the chest is observed, cough improves, easy expectoration is produced, night perspiration diminishes, the face becomes fuller, the lips red, the nails and hair grow, and in children the teeth, showing the importance of the Hypophosphites on the organ of nutrition.

☞ Physicians when prescribing will please write thus:

℞ SYR: HYPOPHOS: COMP: McARTHUR. ONE BOTTLE.

As it is made *only for physicians* there are no printed wrappers or advertisements about the bottle.

Our pamphlet on the **CURABILITY AND TREATMENT OF CONSUMPTION**, sent free to physicians upon application.

We will send one bottle of McArthur's Syrup to any physician, without charge, who will pay the express charges on the same.

Mention this Journal. McARTHUR HYPOPHOSPHITE CO., BOSTON, MASS.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

THE FATALITY OF CARDIAC INJURIES.

BY H. A. HARE, M.D. (UNIV. OF PA.),

DEMONSTRATOR OF THERAPEUTICS AND INSTRUCTOR IN PHYSICAL DIAGNOSIS IN THE MEDICAL DEPARTMENT AND IN PHYSIOLOGY IN THE BIOLOGICAL DEPARTMENT, UNIVERSITY OF PENNSYLVANIA.

The question as to how long a human being can live after an injury to the most vital portion of his body is of the greatest importance from several aspects. In the first place there are a large number of medico-legal points of the most important character involved, not only as to circumstantial evidence in criminal cases, but also as to survivorship, and the ability to perform certain conscious acts after the reception of the wound, such as the signing or destroying of any paper, or the infliction of injuries by way of retaliation by the primarily injured party.

My attention has been called to this matter to a considerable extent of late and particularly by the article published in *Lo Sperimentale*, March, 1889, by Cristiani, Assistant Professor of Forensic Medicine in the University of Pisa, the drift of which is, briefly, as follows: A man aged twenty-five was stabbed, in a brawl, in several places. One wound was in the fifth interspace on the left side, near the anterior axillary line. There was a second wound in the eighth interspace on the same side, extending from the posterior border of the axilla toward the shoulder blade. There was also a stab of the left hip and several stabs on the right arm. After the second wound was received—the one near the præcordia—the man fell, but retained consciousness. After being taken home he was seen by a physician, who found him still conscious, with respirations at fifty a minute and pressing dyspnœa. This state lasted for eight or ten days. The wound over the heart healed in seven days, and that in the eighth interspace in eight days. On the eighteenth day the patient got up, though still weak, and on the thirty-seventh

day, while yet feeling ill, he walked to Pisa and back—a distance of six miles and a quarter. This was done in the morning; in the afternoon of the same day he walked nearly two miles, climbed a tree after a bird's nest, and fell to the ground, dying ten minutes later.

At the autopsy it was found that the wound in the fifth interspace had penetrated the pericardium and deeply wounded the wall of the left ventricle at a distance of three and a half centimeters from the apex, but had not actually entered the ventricle. The mouth of this wound was filled with a soft clot, which was removed and a mass of organized blood-clot was found below it. This mass had ruptured by reason of the increased strain, so that there was an opening into the ventricle through which the fatal hemorrhage took place.

In the same article is a report by Messeri, of Florence, relating the case of a man, thirty years old, who was stabbed in the fourth interspace a half inch to the left of the sternum. When admitted to the hospital he was apparently dying, but he soon recovered, and his wound healed rapidly. Twenty-one days later he asked to be discharged, and when this was refused fell into a rage, stepped into the garden and dropped dead almost at once, with cyanosis and dyspnœa as prominent symptoms. The thorax contained much blood and an opened wound was found in the right ventricle near the sulcus and also a wound of the septum. Messeri also refers to statistics collected by Zanetti, who finds that, in one hundred and fifty-nine cases of wound of the heart, in only ten was the septum injured, and that in seven of these death occurred at once, in one it took place in an hour and a quarter, in another in two hours, while the other patient lived twenty days.

Having recently had occasion to look into this matter myself, I have found in medical literature a number of cases recorded where similar survival after severe injury occurred. Thus, Fischer[1] has collected no less than four hundred and fifty-two cases of injury to the heart and pericardium, in no less than seventy-two of which the patient recovered, while in two hundred and seventy-six death took place at periods varying from one hour to nine months. Death was immediate in one hundred and four cases. Of the seventy-two recoveries, examinations, made long after, in thirty-six of the cases, proved the diagnosis to be absolutely correct. Of these seventy-two cases, ten were punctured wounds, forty-three incised, twelve gunshot, and seven lacerated; fifty were wounds of the heart, and twenty-two of the pericardium.

Purple[1] also records forty-two cases of wounds of the heart in which death did not come on immediately. Randalls records a case of a colored boy who lived sixty-seven days with a number of shot in the heart-muscle, and Ferrus a case in which the patient lived twenty-one days with the heart *transfixed with a skewer*.

It is apparent, therefore, that all wounds of the heart do not cause instant death, or even any lethal ending. Further than this Heil[2] records an instance in which the patient survived a year, and died of another disease, the post-mortem disclosing a cicatrix in the walls of the aorta. Again, in the *Lancet*, 1887, a case is recorded in which a man, 77 years old, made nine punctures with a darning needle in different parts of his body, one of them penetrating the heart. He lived "an hour or more" after the cardiac injury. Wharton and Stillé record several cases; and at least three instances are on record in this city.

In the *American Journal of the Medical Sciences*, July, 1861, a case is recorded in which a bullet was imbedded in the heart for 20 years; and as long ago as 1829 Dr. Redman Coxe contributed a paper on this subject to the journal just named. Lamballe, in the *Archives Gén. de Méd.* for September, 1839, has also contributed a valuable paper upon this question.

Ollivier and Lawson[3] have collected 29 instances of penetrating heart wounds, of which only two proved fatal within 48 hours; the rest of the subjects died in from four to twenty-eight days after receiving the injury. The Duc de Berri lived eight hours after a wound of the left ventricle; and Watson saw a case in which a man ran eighteen yards after such a wound. Those who are interested as to further discussion of this subject I may refer to the paper of Mesbrenier in the *Annales d'Hygiene*, 1879, i, p. 257.

These observations and reports are of sufficient interest to show that careful statements should be made by physicians when called to the witness-stand, and to make it evident that a wound of the heart is in itself not necessarily fatal, and that the fatality of such a wound depends upon

the hemorrhage which ensues from a complete solution of continuity of the heart wall or an involvement of the nervous ganglia in the heart substance.

This communication has been made by me rather in the sense of a preliminary note, and I am now carrying out a series of experiments on the heart of the lower animals, with the object of obtaining material for practical deductions, both medico-legal and surgical, and which I hope to place on record before the lapse of many weeks.

117 S. 22d street, Philadelphia.

THE VENTILATION OF CITIES, OR THE SANITARY VALUE OF INTERIOR OPEN SPACES.[1]

BY J. M. ANDERS, M.D.,
PHILADELPHIA.

Large cities cannot afford to be systematically neglectful in regard to sanitary matters. Human life and public health are too valuable to be estimated in dollars and cents. Wherever human beings congregate, a plentiful supply of fresh pure air in constant movement is necessary to the preservation of sound health. A stagnant air is slowly but surely mortal. Among the sanitary needs of a city, good ventilation ranks second to none. In this connection, the question of open spaces in cities is far-reaching in its relation to the cause of many of the more commonly prevailing as well as most fatal diseases; and it also involves a consideration of the ill effects of overcrowding, which is caused largely by the tenement system of building houses, by high buildings, narrow streets, and by small counting-rooms.

It is to be noted that the rate of increase in population of cities and their growth in area are not, as a rule, in equal ratio. As pointed out by Professor E. R. L. Gould,[2] "they grow rapidly in height, but not so fast in length or breadth." The comparative growth of urban and non-urban populations during thirty years is also mentioned by Gould, who writes: "In the United States, in 1850, the inhabitants of cities amounted to 12.5 in each 100 of the total population; in 1880 the number had advanced to 22.5, an increase of 80 per cent."

For the last quarter of a century there has been observed an increasing popular sentiment in favor of small parks. This favorable change of public opinion is due largely to the fact that, wherever open spaces have been created in populous centres, they have proved of incalculable benefit in a great variety of ways.

No member of the medical profession, knowing the importance to sound health of pure fresh air and sunlight, can reflect upon the unfortunate state of society as met with in some of the worst quarters of large cities, where persons are often packed together without the slightest regard to the proper cubic air-space per head, and escape the conviction that something ought to be done speedily to bring relief to all who are exposed to these pernicious influences. That the powers of the human system are intolerant of the baneful effects of overcrowding is no new fact in medical science. Massing a population unduly lowers the general vitality and favors the development of such diseases as rickets, anæmia, phthisis, and others. There is also a group of infectious and contagious diseases—more especially measles, scarlatina, diphtheria and typhoid fever—for whose propagation densely populated districts, where natural ventilation is defective, furnish a good breeding-ground.

All sanitary authorities agree that the cubic air-space per head should not be less than one thousand cubic feet, and that the air of this space should be thrice renewed every hour, if we would prevent undue accumulation of noxious organic substances which are given off in respiration and by the skin. Perhaps all except our best homes fall short of this hygienic requirement; and certain it is that in the homes of the poor the average cubic space per head is reduced to less than one-third of that mentioned as necessary.

Wilson,[1] speaking with special reference to society as found in European cities, states that among the poorer classes the cubic space for each person, instead of approaching to one thousand feet, in numbers of cases does not amount to two hundred feet. In the tenement houses of New York City and Brooklyn we have the most impressive example of the evil consequences of the massing of a population to be found in the United States. One of the wards in New York City has over 290,000 persons to the square mile, and several have a population of 200,000 to the same area. One-half of the whole population, indeed, lives in these houses, while more than seventy-five per

[1] Intended to be read before the Medical Society of the State of Pennsylvania, June 5, 1889.

[2] Open Spaces in Cities.

[1] Text-Book of Hygiene, p. 252.

cent. of all deaths occur here. In view of the hygienic truth that the mortality rate increases with the density of the population, the fact that not many years since the death rate in New York City was 28 in 1000 per annum will excite no surprise. And we need not wonder at the declaration of an eminent authority when he states that there is no third generation in many New York tenement houses.

Time was when the chances of life were twice as good in the rural districts of England as in Liverpool and Manchester,[1] and less than half a century ago the mortality rate of nearly all great cities bore to sparsely populated rural districts about the same ratio.

Within the last twenty-five years, however, all this has been greatly changed; the annual average death rate in many of the older cities has already been reduced by nearly one-half. To some extent this has been occasioned by the enforcement of better sanitary rules and regulations, more especially such as pertain to the drainage, on the part of local and state boards of health, and also by a better knowledge of hygienic principles and the spreading of that knowledge among the people. But it has been clearly observed that, in consequence of having created new interior open spaces and public parks and having widened their thoroughfares, thereby securing a better system of outdoor ventilation for the people, many of the older European cities have greatly assisted in lowering their mortality rate.

The sanitary importance of ventilating the home is universally acknowledged. But a perfect system of ventilation implies that the air admitted to our dwellings shall be pure. Now this cannot be the case in districts where the buildings are high, the streets narrow and tortuous, often near alleys and occupied by a dense population, and with light and fresh air practically excluded. Surely under these conditions foul air is abundantly generated and filth especially accumulates. In cities, an efficient system of indoor ventilation must go hand in hand with an efficient system of outdoor ventilation, the one always implying the other. In order to secure a proper air movement and a plentiful supply of fresh air, the streets should be wide, and frequently recurring small breathing spaces should be introduced, especially in overcrowded parts; thus to some extent scattering the population, on the one hand, and admitting sunlight and fresh air on the other.

Open spaces act as powerful ventilators of large cities, not only by diluting any impurities that may be present, but also by their favorable influence in promoting mild wind-currents. This is especially true where public squares communicate with wide avenues or streets open at each end. With a view of showing the great importance of interior open spaces to the best interests of the inhabitants of large cities, we have the testimony of Dr. T. Newell.[1] This author, speaking with reference to London, a city liberally provided with park areas, says: "Reckoning the population of London at 4,100,000, the reduction in the death rate during the last two hundred years shows a saving of 91,020 lives for the year 1886, more than two-thirds of the population of Providence. The extravagant employment of 'fresh air' and 'elbow room' has doubtless been the most important factor in bringing about this desirable change."

As showing the favorable influence of wide streets over the prevalence of phthisis, we also have the results of the very interesting observations by Dr. Arthur Ransome upon the causes of this disease, in Manchester, England. He writes: "The longest and widest streets in the district were Jersey Street, with ten deaths, and George Street, with eight deaths; but the number in these streets is approached by the mortality of eight deaths in Hood Street, which is only half its length, but which is a mere lane, blocked at each end, so as to obstruct free ventilation. Again, Henry Street, which is a long thoroughfare, has only four such deaths, while Boord Street, a narrow *cul-de-sac*, only a quarter its length, has seven." Dr. Ransome's investigations furnish fresh evidence of the fact that some of the most fatal as well as most prevalent diseases are to a great extent within human control, and that these would lose much of their terror if more decided measures were adopted to prevent them.

So much for the sanitary effects of city air-holes as mere open spaces; much might be said concerning their hygienic value when treated of as spaces filled with growing vegetation. The salutary influence of living plants upon the air, however, having received a good deal of attention during the last decade, will here be dismissed with the mere enumeration of a few well-established facts. The effect of a space filled with growing trees and shrubbery is to

[1] Twenty-fifth Report of the Registrar General.

[1] Interior Open Spaces in Cities, 1889.

increase slightly the local degree of saturation and to maintain its equability; to increase the ozonizing power of the atmosphere, thus rendering it safer and purer; to furnish grateful shade, which also has a cooling effect upon the air in summer, and to exercise a well-known moral or æsthetic influence.

This question also has its humanitarian aspects. Every large city has its toiling multitude, which cannot get a change of air during the heated term—cannot even, for want of means and time, reach the larger parks and pleasure grounds, which may be but a few miles distant from the scenes of their daily labor. For this large class, as well as the sick children of workingmen, numerous open spaces, at short distances from each other, though they are small, would, as before stated, be of incalculable benefit as places in which to spend a brief period for refreshing and healthful recreation.

The members of this Society may be interested in knowing what provision has been made by certain leading foreign and American cities in the direction of public parks for the people. The subjoined tables show the park acreage as well as the proportionate population per acre.[1]

PARK ACREAGE OF CITIES OF THE UNITED STATES.

	Population.	Park Acreage.	Population per Acre.
Providence	123,000	123	1,000
Boston	400,000	2,000	200
New York	1,839,000	4,902	375
Philadelphia	971,363	3,000	323
Brooklyn	665,600	940	639
Chicago	704,000	3,000	234
St. Louis	400,000	2,232	179
Washington	205,000	1.000	205
Baltimore	355,000	832	439
Cincinnati	325,000	539	603
San Francisco	270,000	1,181	211
Buffalo	202,000	620	326
Detroit	175,000	740	204
Minneapolis	129,200	808	159
Savannah	33,000	60	550
New Haven	80,000	384	208
Bridgeport	40,000	240	170
Worcester	68,000	280	243
Pittsburgh	156,389	1.25	120,299

FOREIGN CITIES.

	Population.	Park Acreage.	Population per Acre.
London	3,832,000	22,000	174
Paris	2,270,000	58,000	37
Berlin	1,122,000	5,000	229
Vienna	1,103,000	8,000	138
Brussels	380,000	1,000	380

Montreal	120,000	550	218

[1] Dr. T. Newell, Interior Open Spaces.

From a glance at the foregoing tables it is seen that there is great diversity in the extent of the park area in proportion to the population. Among the cities having the smallest park surface are Providence, Brooklyn, Cincinnati, Savannah, and Pittsburgh, the last named having only one and one-third acres, and, although it may appear strange, this small open space is said to be difficult to locate. I may be excused for stating that it is a disgrace to Pittsburgh that it cannot afford more play-grounds for the children and breathing-spaces for their parents. The inhabitants of this enterprising city should remember that to continue to disbelieve in fresh air will inevitably lead to physical degeneration.

Dr. Gould,[1] in a recent article, has formulated a table giving a classification of open spaces as to size, together with the largest open space in acres for certain American cities. What will strike the reader of this table most is the tendency in cities to large parks and the absence of a liberal number of small open spaces in the squalid portions in which the population is densely herded together, and where light and air are most needed.

In conclusion, it should be pointed out that some of our leading American cities are making provision for new open spaces. Indeed, there is scarcely a representative city—excepting Pittsburgh, of course—in the Union which is not to-day bestowing some attention upon the subject of its interior adornment by means of parks and other open spaces, as well as wide and long park-ways; and this is not a question demanding the attention merely of physicians and leaders in social reform, but of all citizens also.

Washington can boast of an ideal park system, with which that of no other city can be compared. In 1866, Chicago began to take decided steps toward creating public parks, and it now ranks next to Washington in point of desirable features in the arrangement of its interior open spaces. In Boston the subject has been before the people for many years, and the excellent results accomplished there are well known to students of municipal history; and the same thing is true of St. Paul, Minneapolis, and of Providence. In New York the movement began in 1881, and already much has been done in the direction of opening up new pleasure grounds. As late as May, 1888, Philadel-

[1] Park Areas and Open Spaces in American and European Cities. Reprint from publications of the American Statistical Association.

phia was awakened to the necessity of creating additional park areas through the influence of a few public-spirited men and women, who about the same time formed the "City Parks Association." This is an active organization which has already achieved excellent results and has been the means of giving Philadelphia five new and valuable public parks.

ANTISEPTICS IN NORMAL LABOR.[1]

BY G. W. H. KEMPER, M.D.,
MUNCIE, IND.

I have practised medicine in civil life twenty-four years, and during that time have attended nine hundred cases of labor, recording a concise history of each case. This number does not include cases I have seen in consultation. In none of the nine hundred cases have I used a single antiseptic measure—in the sense that we apply that term at the present day. I have refused to attend obstetrical cases when I was treating bad cases of erysipelas and scarlet fever, although I have attended a woman and performed version, while her husband was lying in an adjoining room with facial erysipelas. I have, also, attended a woman in confinement who was suffering with phlegmonous erysipelas at the time; and yet, fortunately, no untoward results occurred. I have tried to prevent myself from becoming a "walking pestilence," and aimed to go to every case with "clean hands." I have, when consulted, given proper advice to women in their approaching confinement; but I have never administered, nor caused to be administered, to any woman, any of the popular antiseptic remedies before or after parturition.

Of my nine hundred cases, two of the women died. The first one died as the result of puerperal convulsions, on the seventh day after her confinement, and the second died of acute pneumonia, on the ninth day after her confinement, the iniatory chill having occurred the day preceding the labor. Both women were primiparæ. I have met with no severe case of puerperal fever among my nine hundred cases. To prove that my cases were of the average gravity, I will add the following statistics: of the 900 cases, 299 were primiparæ, and 601 multiparæ. There were 13 cases of twins, and 887 single births; so that 913 children were born. Of these, 874 presented by one of the several head presentations; 36 were breech or footling, and 3 were shoulder presentations. I had 8 cases of puerperal convulsions; 9 cases of *post-partum* hemorrhage; 8 cases of adhesion of placenta, and 4 cases of placenta prævia. I performed version three times, and cephalic version once. In one case inversion of the uterus followed the expulsion of the placenta, and was corrected at once. Finally, I used the forceps 27 times.

My practice reaches back to a period antecedent to the days of Listerism—to days when we had not heard of the new "Gospel of Antiseptics." Prior to that time, I met with cases that would properly have been treated by this class of agents. For instance, I reported a case to this Society in which a dead fetus was carried in the uterus for four or five months, to the great detriment of the mother; and I have met with a few other instances in which the fetus had been dead for a shorter period. In all of these cases, with no vaginal irrigations, the patients made a good and speedy recovery. Suppose that in all these cases I had used medicated injections into the uterus, and applied pads to the vulva; what valuable encomiums I could bestow upon the practice—the *post hoc ergo propter hoc* error.

In presenting my views upon this subject, I am quite aware that I shall antagonize the opinion of gentlemen who hear me. At the meeting of the Indiana State Medical Society last year, when my friend, Dr. L. N. Davis, read his paper on the "Progress, Practice and Obstetrical Record of the Country Doctor," it was apparent that some of his statistics were disbelieved. He stated the mortality of several country practitioners, residing in his locality, as follows:

Dr. J. T. Chenoweth,	1600	labors.	1	death.
" Thomas Botkin,	525	"	5	deaths.
" N. T. Chenoweth,	708	"	2	"
" A. H. Farquhar,	500	"	2	"
" J. S. Blair, . .	419	"	2	"
Total, . .	3752		12	

No antiseptic precautions had been taken in the practice of these five physicians, and yet the total rate of mortality to mothers, in 3,752 labors, was 12, or one in every 312. I have the honor of a personal acquaintance with the physicians just mentioned, and, when they furnish obstetrical statistics, I trust them as implicitly as I do statistics furnished by physicians in lying-in hospitals. I am not aware that a country prac-

[1] Read at the meeting of the Indiana State Medical Society, May 2, 1889.

titioner is more prone to exaggeration than his city brother, nor have I understood veracity to be an exclusively urban product, or that falsity was indigenous to rural localities. Who furnished the wonderful obstetrical statistics collated by Churchill? Were they not masters in lying-in hospitals? And so our statistics at the present day are largely compiled from hospital records. For this reason, when statistics are furnished by men who practise in healthy, rural districts and the mortality is shown to be light, skeptics are disposed to charge a *suppressio veri*.

A class of recent converts to antiseptic measures has sprung up in this country and has introduced the practice into lying-in hospitals. Great success has attended their labors, and they are deserving of praise; for the death-rate has been very materially lessened. In their great zeal in this good work they blindly accuse all who do not avail themselves of these aids, of criminal negligence. A striking example of this indiscriminate accusation is found in the "American System of Obstetrics." Dr. George J. Engelmann contributes an article to the first volume, on the "History of Obstetrics"; and, on page 64, in speaking of antiseptics, uses this extravagant language: "Such is the perfection of obstetric art in the hands of the masters of the art, and in lying-in institutions; whilst in private practice, in the homes of comfort, with the attendance of the best practitioners and the care of good nurses, many a young mother yields her life to the dangers which still accompany home confinement. We are told that the records of a prominent insurance company reveal a mortality of 17 *per cent.* in private practice, and that among the better classes." It is remarkable that Dr. Engelmann should allow the statement that "the records of a prominent life insurance company reveal a mortality of 17 per cent. in private practice, and that among the better classes," to pass unchallenged. In a foot-note, the Editor, Dr. Hirst, corrects the error, and says: "Extensive investigation has shown the mortality of confinement cases in general practice to be about 1 *per cent.*" If Dr. Engelmann and Dr. Hirst design these figures to indicate the mortality of child-birth in the cities, I have no facts bearing upon the question either for proof or for disproof. The statistics I have furnished to-day show that even the ratio of 1 *per cent.* is entirely too high for our country practice. Dr. Bradbury, Health Officer of Delaware County, in which I reside, informs me that during a period of six years and eight months, in which records have been kept in that county, 4,444 women have been delivered, and of that number 34 died—a ratio of about seven and a half deaths to 1000. This mortality represents the practice of all kinds and qualities of practitioners, including midwives. Ten of the thirty-four women died from accidents which were not amenable in the least degree to antiseptic precautions. Hence our country practice, in the hands of promiscuous practitioners, without antiseptics, presents a more favorable aspect than does the hospital practice in large cities, with antiseptic precautions.

Probably Dr. H. J. Garrigues, of New York, is one of the most ardent, if not the greatest, advocate of antiseptic midwifery in this country, as shown by his work on that subject, which was published last year. I quote from his book: "I believe that by far the greatest number of general practitioners yet conduct their deliveries in the same way that they learned at college many years ago, and which they have been accustomed to follow since they began to practice.

"Some tell us, when the question is discussed in our public societies, that they have delivered so and so many thousand women, and never lost one of puerperal fever, and they have never used other precautions than common cleanliness. Either their memory fails them, or they have a convenient definition of puerperal fever; in consequence of which puerperæ die of peritonitis, metritis, pneumonia, pleurisy, heart disease, liver complaint, kidney trouble, meningitis, typhoid fever, etc., but never of a disease the mere mention of which, septicæmia, would teach the propriety of adopting the antiseptic treatment. To this class I would say, that, if they keep notes of their cases, and will study them in the light of our modern experience, they will find that after all they have not lost so very few patients in child-bed—probably not less than one in a hundred, and that all those diseases of which they have died are precisely the same as those of which our patients used to die in lying-in asylums."

"General practitioners," who "conduct their deliveries in the same way that they learned at college many years ago," may not feel complimented at being told they have learned nothing new since they began to practise midwifery; but they will feel some degree of compensation in learning that a teacher like Dr. Garrigues has made progress and no longer confounds "pneu-

monia, heart disease, liver complaint, kidney troubles, meningitis, and typhoid fever" with puerperal septicæmia! If Dr. Garrigues will take the pains to examine the records of competent general practitioners, he will find that the mortality of lying-in women is not so great as he imagines, and that antiseptics are not a panacea for the mistakes and ignorance of incompetent practitioners. The paraphernalia and details of antiseptic midwifery, as laid down by Thomas, Garrigues, and some other writers, is expensive and tiresome. In hospitals and cities, where the services of trained nurses can be secured, the system can be practised. In the country, as a rule, women are not visited at all after confinement by the attending physician, or only once or twice. In many instances they are left to the care of a member of the family, or more commonly to the care of a servant-girl, who fills, at one and the same time, the responsible positions of nurse, cook, and chambermaid. In cities it is the rule to engage physician and nurse for the lying-in, and needed preparations are made. The reverse is the rule in the country. I have been called to strange homes and greeted at the threshhold with such words as: "Hurry in here, Doctor; this woman needs you quick." And I have, without even the formality of an introduction, witnessed a number of deliveries within five minutes after my entry into the house. In such cases the time for the ante-preparatory, antiseptic treatment of Prof. Thomas would not equal that for the death-bed repentance of a subject of Judge Lynch.

I make no war on antiseptics in general. In surgical practice I observe the rules of our modern teachers and text-books as regards their use. In obstetrical practice I am particular to clean every instrument, by immersing it in boiling water. If the lochia are offensive, I use disinfecting injections; if the perineum be torn, I would sew it under antiseptic precautions. While I would do all this, and even concede more, if necessity would seem to demand it, I do not feel it is necessary in every case of normal labor, when my patient is surrounded by healthy environments, to attempt to carry out a complicated routine of practice which my experience teaches me is unnecessary.

While preparing this paper, I met with an abstract in the *Journal of the American Medical Association*, April 15, 1889, from a letter written by Dr. Robert Barnes to the *British Medical Journal*, that covers the ground of extremists so thoroughly that I will make short quotation from the paper:

"To see in septicæmia the only evil is to fix all therapeutical energy upon what is commonly understood as antiseptic treatment. This is the course advocated by the more earnest of the septicæmic school. Without affirming that they recognize no other remedies, it is not too much to say that they carry the practice of antiseptic irrigations to an irrational extreme and to the comparative neglect of other important indications. They assume on the other hand that those who deny the exclusive dogma of septicæmia are stricken with therapeutical impotence. 'The doctrine of autogenesis,' exclaims Parvin, 'is a confession of ignorance, the creed of fatalism, the cry of despair . . . the very pessimism of obstetric medicine.' Big words, full of sound, and little else. The truth is that those who take a broad, comprehensive, catholic view of the many factors in the etiology and constitution of puerperal fevers take also a broader, more philosophical, and more rational grasp of the principles of treatment and especially of prophylaxis. . . . The essential thing is to take such a large view of the physiological and pathological processes as will give the right indications to call upon each and all of the therapeutical agents at our command. To fix the mind too intently upon any one of these agents is to incur the danger of neglecting others, and of losing sight of the principles which ought to guide the applications of all as one force directed to one end."

In conclusion I beg leave to submit the following aphorisms:

1. The history of obstetrical practice teaches us that the lying-in hospital has always been a place of danger and mortality; therefore, it is obligatory upon those who have charge of these institutions to utilize every antiseptic measure known to the profession in order to save life.

2. The experience of country practitioners teaches us that women who are confined in healthy, isolated, rural homes are not subject to the contaminating influences of an ochlesis, and consequently do not require all the precautions of those exposed to hospitals, or even to the atmosphere of city life.

3. Country practitioners of medicine will generally show a lower rate of mortality in obstetrical cases than city practitioners, simply for the reason that they practise in

healthier localities, are less exposed to contagious influences, and, possibly, have a healthier class of patients.

4. The insinuations of a number of late writers on antiseptic midwifery, that the death-rate in obstetrical practice of country practitioners is high, are not true, as is shown by statistics.

THE VALUE OF CHLORAL HYDRATE.

BY JEROME HARDCASTLE, M.D.,
CECILTON, MD.

The following cases, occurring in my practice, have made such an impression on my mind in regard to the value of chloral hydrate in the treatment of a variety of conditions requiring a calmative, that I have thought it might be worth while to describe them briefly to my professional brethren.

CASE I. *Puerperal Eclampsia.*—Mrs. N.; aet. 19; primipara; after eight hours' normal labor was delivered of a ten pound boy. For two hours previous to her delivery she had complained of intense cephalalgia; about half an hour after delivery convulsions came on and the patient had two within about half hour. I gave an enema of chloral hydrat, gr. xc, to aq. tepid f ʒ ij, and applied a napkin to the anus, to retain it. The woman had one slight convulsion soon after, and, in one hour from the time of giving the first enema, I repeated it, when a quiet and refreshing sleep of four hours was followed by satisfactory convalescence.

CASE II. *Puerperal Eclampsia.*—Julia, colored; aet. 28; multipara; had suffered from cephalalgia from the beginning of labor. In about four hours convulsions set in, and during the fifth one a girl child was expelled. After a short interval, the convulsions returned. I then gave an enema of chloral and she had no further trouble.

CASE III. *Threatened Miscarriage.*—Mrs. S.; aet. 20; primipara; 7 months advanced; on going out the door fell upon her abdomen. Expulsive pains and uterine hemorrhage ensued. Arriving about one hour after the accident, I found the bed and her clothing saturated, the amniotic membranes distended and protruding through the os uteri, which was dilated to about the size of a walnut. I gave an enema containing 90 grains of chloral and applied cold cloths. In about an hour I used 60 grains more. The pains and hemorrhage then soon ceased, and the patient slept several hours. Three days after she was up and at work. At the expiration of nine months she was delivered of a girl. The child was anemic and fainted from slight causes during the first three years of its life; since which time (the parents having removed) I have not been able to trace its further history.

CASE IV. *Threatened Miscarriage.*—Mrs. H.; aet. 25; multipara; six months advanced; two weeks previous to my visit fell upon her abdomen and had slight pains, which lasted several hours. Upon seeing her I found that the pains had begun three hours before and recurred about every seven minutes. There was no hemorrhage and no perceptible dilatation of the os. I gave 90 grains of chloral by enema, and as the pains did not cease entirely in one hour I gave 60 grs. more. In half an hour she was sleeping quietly. She remained in her room three days, and then resumed her duties, and now, nearly four weeks having elapsed, I find her doing well.

CASE V. *Epilepsy.*—Jim; colored; aet. 8; birth had been effected by forceps; convulsions began to occur soon after and continued about five years, with increasing frequency. His treatment had been with bromides, etc. When called to see him, three years ago, I found that he had been having convulsions about every week, and from six to thirty or more during the day and night. I gave an enema containing ten grains of chloral *hourly* till relieved. Improvement was very marked. Intervals of a month or more came between the attacks, and there were only from two to four. For the past one and a half years the boy has had only one convulsion every three months (*or four a year*), his general health is good, his memory is much better, and his previously quarrelsome disposition has almost deserted him.

CASE VI. *Eclampsia from Dentition.*—Child; aet. 18 months; suffered with convulsions several hours before I saw it. I gave an enema containing eight grains of chloral, and scarified the gums. Two slight tremors occurred afterward, and the child went to sleep and awoke in about six hours as bright as a dollar.

CASE VII. *Eclampsia from Ascarides.*—Child; aet. 3. I gave fifteen grains of chloral by enema and applied a cold cloth to the head and gave a hot mustard foot-bath. During an hour the child had two more convulsions. At the expiration of this time, I gave ten grains more, and sleep followed for four hours. I then ordered a powder containing calomel, santonin and

soda, every two hours until four were taken, and the next morning ol. ricini f ℥ss; spir. terebinth. gtt. xxx. During the following day the child passed a number of worms, and made a good recovery.

As an anti-convulsive I know of no remedy that equals chloral used in the manner above described. It is often impossible to give it by the mouth, and when it can be given so, its effects are much slower, and it is frequently rejected. I do not think it safe to exhibit chloroform or ether by inhalation, and chloral by the mouth at the same time, as I know of two cases—one surgical, the other obstetrical—in which in the former the patient suddenly expired while being prepared for the operation, and in the latter prompt and energetic measures alone saved her. In the case of Mrs. N. (puerperal eclampsia), mentioned above, I used chloroform inhalations freely and chloral *by enema*, and had no untoward symptoms.

Society Reports.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, May 27, 1889.

The President, Alexander S. Hunter, M.D., in the Chair.

Dr. A. Jacobi read a paper on

Rheumatism in Infancy and Childhood.

He first alluded to the limited bibliography of rheumatism in infancy and childhood. It began with theses on the subject by two of Roger's pupils, written in 1864 and 1865, and with a paper by Roger himself, in 1867; between this time and 1875, when Dr. Jacobi wrote on the subject in this country, about half a dozen other papers had appeared. In 1885, the study was renewed. Dr. Jacobi, on the present occasion, chiefly considered the question of therapeutics of rheumatism in infancy and childhood, although he spoke briefly of some other points. Since he made the statement, fourteen years ago, that these cases occur frequently, only a few have come to recognize the truth which it contains. He thinks the frequent presence of cardiac disease in childhood sufficient proof of the common enough existence of rheumatism. Then there are also cases of rheumatism at this period which manifest no cardiac disease whatever. Wherever there is any doubt or suspicion of its existence, the heart should be carefully examined; for often the cardiac affection appears to be the first, and perhaps the only clear, symptom of rheumatism. The presence of chorea minor should also lead to a careful examination of the heart and joints, for in not a few cases it is seen at even the very beginning of rheumatism.

The diagnosis in many cases is quite difficult. Fever is a common symptom, but it is also common in any physical disturbance in children. The temperature is sometimes only slightly elevated, and sometimes rises at irregular intervals. The swelling of the joint is apt to be only trifling; and the pain, either arising from pressure or spontaneously, may simulate that due to fatigue, syphilitic disease, etc. The diagnosis is more difficult when only one joint is affected, especially if it is the knee- or hip-joint, which is also often the seat of traumatism and tubercular inflammation. Rheumatism also frequently fails to be recognized because the pains are called "growing pains," a term which should have been dropped long since. Epiphysitis has likewise been confounded with rheumatism.

Turning to the subject of therapeutics, Dr. Jacobi said it has been quite unsatisfactory until modern times. A few indications are furnished by the actual or alleged causes of the disease. For instance, it seems sometimes to be endemic, and when it is so, it is well to remove the child to another locality. It occurs frequently after typhoid fever, diphtheria, scarlet fever, and other infectious diseases; and one should avail himself of this knowledge in prophylaxis. The blood has been found changed in rheumatic fever, being less alkaline; and while this fact is not peculiar to this disease, yet it affords an indication for alkalies, and experience has shown that they are beneficial.

Sudden changes of temperature and of moisture certainly favor the development of rheumatism, especially in those of inherited predisposition. The tendency to be influenced by atmospheric conditions can be modified by the systematic use of cold water. Warm clothing and bedding are called for, as nothing can be more injurious to these patients than exposure to wind and rain.

The swollen and painful joints must be protected against the pressure of blankets by raising the bed-clothing from the limbs, as by inserting the limb through a waste-basket. A wet bandage or pack around the joint is often borne well and is grateful. It should be changed every hour or half hour.

Anæmic children require hot applications, perhaps dry. In very severe cases Dr. Jacobi has sometimes been compelled to administer a few drops of a solution of morphine hypodermically; but as a rule an anodyne applied around the joint, and covered with oiled silk, gives relief from pain. Swelling during convalescence may call for pressure, which can be exerted by means of bandages or collodion, absorption being hastened by gentle massage and the galvanic current, and by the internal administration of iodide of potassium or sodium. He brushes copiously over the swollen part iodoform in collodion. Very old cases with chronic effusion into the joint require aspiration and washing out of the joint.

Endocarditis demands for its treatment absolute rest of the heart and body. For that reason an occasional dose of the bromides or of opium may be beneficial. The ice bag to the præcordial region, or, if that be too heavy, the ice cloth, will do good. It should be remembered, however, that not every murmur indicates endocarditis.

The temperature is rarely high, but there are some cases in which it rises to 104°, or even 107° or more; and in this class occur delirium and other nervous symptoms. The most effective means of reducing the temperature is by the cold pack. Antifebrin, antipyrin, and phenacetine may here be called for. As a rule, salicylate of sodium mitigates the pain, etc., in a short time; but if it produces no effect within from three to five days it should be discontinued. As already stated, alkalies are indicated, and may be administered in the form of bicarbonate of sodium, or of the nitrates, or of the mineral waters. Vegetable acids have been warmly recommended by some. Iodide of potassium and sodium have been justly commended highly, especially where the case shows a tendency to chronicity.

Gonorrhœal rheumatism is sometimes seen in children. It is for the most part confined to one or two joints, as the ankle or shoulder, and is of a subacute nature. The effusion is likely to be excessive, often purulent, and suggests a relationship with pyæmia. A puncture may be made for the purpose of ascertaining the nature of the effusion, and if pus be discovered it should be removed and the cavity thoroughly disinfected. Salicylate of sodium or iodide of potassium and sodium should be continued a long time in these cases. In some cases, during and after an attack of acute rheumatism, small nodes develop in the fascia and periosteum, consisting of young connective tissue, which are tender, and last from a few days to several months. In a few cases there are hemorrhagic spots. Salicylate of sodium tends rather to promote hemorrhage.

Chronic articular rheumatism is rare in childhood. The treatment is about the same as that of the same disease in adults. Salicylate of sodium is to be administered in these cases only when there is an acute exacerbation. The so-called hydropathic treatment is beneficial. Alkaline waters are necessary, and Dr. Jacobi strongly recommends lithia water to which bicarbonate of sodium has been added.

Muscular rheumatism can be diagnosticated occasionally in very young children; but in children from six to twelve years of age it is not very rare. The neck, back and shoulders are most affected. The best preventive measure is the habitual use of cold water.

Dr. William H. Thomson said his attention has long ago been called to the influence of climate. It has been said that a cause of rheumatism is cold and moisture; yet it is a common disease among the Arabs and inhabitants of the Desert of Syria, where the climate is very dry and hot during the day. There is one condition, however, to which these people are exposed in common with the inhabitants of cold and moist countries, namely, that the moist skin suddenly becomes cooled during the night following the hot days. This he regards as an important etiological fact. It is an important one also in the differential diagnosis between rheumatism and gout. The latter affection is seen only among persons who use alcoholic drinks, and is due to some error in assimilation. The character of the pulse will distinguish the one affection from the other, it being incompressible and hard in gout, and soft and compressible in rheumatism. Dr. Thomson is disposed to think that in scarlatinal rheumatism there is an approach to a pyæmic condition. He has also in a certain number of cases found an invariable association of acute articular rheumatism and quinsy.

In therapeutics he has a great fondness for the continued use of the warm bath. Among other effects, it is anæsthetic and also renders the urine alkaline. The rheumatic should always wear flannel next the skin. As a further prophylactic he has these subjects use inunctions, especially on the back of the neck and shoulders. He also administers cod-liver oil in chronic rheumatism. He emphasizes the necessity for giving

attention to rheumatism in children on account of the injurious consequences of heart complication. There is no doubt in his mind that a relation exists between chorea and rheumatism. Chorea, so to speak, is a result of the rheumatic poison. In treating endocarditis, he places no reliance upon salicylate of sodium for the treatment of the disease, but like all others he administers it for the joint affection. To slow the heart's action, he gives full doses of aconite. At the same time he renders the blood alkaline. The chest should be protected absolutely against drafts, and for that reason he does not allow it to remain bare under any circumstances.

Dr. J. Lewis Smith gave the results of his experience at the Out-door Department of Bellevue Hospital during the past fifteen years. In this time he has made the diagnosis of rheumatism in seventy-eight patients under fifteen years of age, nearly all of them under twelve, the majority about the age of eight years. Most of the children did not have rheumatism when brought to the clinic, but the presence of cardiac disease and the past history in many cases formed the basis of the diagnosis. He has seen a number of cases in private practice also, but has not the records. In general, rheumatism in children under two years of age is accompanied by little swelling, and the diagnosis is difficult. In the majority of cases the disease manifests itself in the lower extremities. Parents are apt to call the trouble "growing pains." Of his seventy-eight cases, forty-nine had distinct cardiac murmurs. As to chorea minor, during the same period he has records of sixty-seven cases, in forty-seven of which rheumatism could be excluded. He has been in the habit of using salicylate of sodium or salicylic acid in the rheumatism of children. It is important to stop the disease and prevent endocarditis.

—The Philadelphia *Telegraph*, May 3, says that Dr. Joseph Rogers, whose death was recently announced, was a native of Westmeon, Petersfield, Hants, England, where his great-grandfather, grandfather, father, and brother practised medicine for a century and a quarter. He was the thirteenth of sixteen children, of whom five became doctors. One of his brothers is Professor Thorold Rogers. He was the founder of the Anti-Interment in Towns Association, and for many years was foremost among the sanitary reformers of England.

Hospital Notes.

CANTON HOSPITAL, CANTON, CHINA.

SERVICE OF J. M. SWAN, M.D.

Opium Poisoning Treated with Atropia Sulphate.

Case I.—April 2, 1889, at four o'clock P. M., I was called into the city to see a Manchu, aged thirty-six years; occupation soldier; married; his family consisting of a wife and three children. About three hours before the time I saw him, he had swallowed a quantity of opium, with the intention of committing suicide. The amount was estimated at about an ounce and a half of the native prepared, watery extract of opium, which is used in smoking. I found his respirations eight to ten per minute; his pulse 80, full and strong; his pupils contracted to the size of a pin head; and, with considerable difficulty, he could be roused, but not to full consciousness. One twenty-fourth of a grain of atropia sulph. was administered hypodermically, and the stomach-pump was at once introduced, and the stomach thoroughly washed out. There was a strong odor of opium given off from the contents withdrawn from the stomach, but no opium was discovered. A dram of brandy in hot water was administered by the mouth, the hypodermic injections of atropia being continued every ten or fifteen minutes.

At first the patient seemed to improve; but soon the narcosis became deeper. As I worked at great disadvantage and with poor assistants, I had the patient placed in a Sedan chair and rapidly conveyed to the hospital. This consumed about twenty minutes, and when the man was brought into the hospital ward his respirations were not over three per minute; there was no radial pulse; his heart sounds were distinctly audible, but feeble; and deep cyanosis was present. One-twelfth of a grain of atropine was at once given hypodermically, his feet and legs were plunged into hot water up to his knees, and artificial respiration was begun. In ten minutes the second one-twelfth grain of atropine was given, the foot-bath being kept as hot as was at all safe without danger of scalding. Very shortly after a third one-twelfth grain dose of atropia was given, the character of the respirations changed. The inspiration became deeper and spasmodic or catching in char-

acter, showing a marked stimulus of the respiratory centre. The respirations were now five or six per minute, and the pupils partly dilated. Hypodermic injections of brandy were administered three or four times during the evening. The respirations and the pulse slowly but gradually improved, and the stimulated respirations were quite marked during the greater part of the night.

The next morning the patient, though still rather drowsy and depressed, was able to take some nourishment, and by ten o'clock A. M. he was able to sit alone on his bed. Late in the afternoon of the same day he was quite himself again.

There is a diversity of opinion as to the real value of belladonna, or its alkaloid, in cases of opium poisoning. From a physiological point of view we certainly have a strong argument in favor of its use. The best proof of its efficiency is in the practical test. In the case reported above, the physiological effects of the drug were well marked, but not until about *three-fourths of a grain* had been administered. I believe its free use saved the life of the patient. This opinion is not based on my experience in this case alone, but also on my past experience; for, in two cases, in particular, of opium poisoning did I attribute success in treatment to the use of atropine.

Cases of opium poisoning are quite commonly met with among the Chinese, and it is the usual means by which they often commit suicide.

Dentigerous Cyst of the Antrum of Highmore—Operation.

Case II.—March 12, 1889, Mr. Tsing Chan, aged 20, unmarried, by occupation a farmer, presented himself for the removal of a growth situated on the right side of the face. It had been present for three years, and had been gradually increasing in size. It involved the outer surface of the right superior maxillary bone from the insertion of the lateral incisor tooth to that of the first molar, the facial surface of the bone having been pushed outward and upward. Part of the teeth were loosened but none were thrown out of line. Over a small area external to the alveolar process, and at a point over the orbital, there was distinct fluctuation. The roof of the mouth was undisturbed. There was no history of pain having been present to any marked degree, and the man's general condition was fairly good, though he did not present a very robust appearance.

March 19, the patient was operated upon. A trochar was first introduced at the lower point of fluctuation, and about two ounces of a thin brownish serous fluid were drawn off. An incision was made extending from a point on the upper lip one inch to the right of the median line, upward and outward external to the infra-orbital foramen, thus avoiding the trunks of the infra-orbital artery and nerve, the incision being fully three inches in length. The teeth involved were extracted, and the facial surface of the bone was removed with a small portion of the sac of the tumor, thus exposing the antrum, which was greatly enlarged and lined with the sac. In the posterior part of the cavity there was a fully developed tooth, corresponding in appearance to a lateral incisor, firmly inserted into that portion of the bone lying beneath the floor of the orbit; and from its length it must have reached very nearly through the floor of the orbit. This tooth having been extracted, the entire sac was easily removed, it being but loosely adherent to the bony walls of the cavity. The sac presented a peculiar velvety appearance, and was one-fourth inch in thickness and exceedingly tenacious. The cavity was filled with absorbent lint and the incision carefully closed, an aperature being left external to the alveolar process, for the purpose of dressing and the daily injection of a ten per cent. solution of boracic acid.

The external incision united by first intention, and at this date—twenty-two days after the operation—the cavity is almost closed, and scarcely any deformity is noticed.

Doubt was entertained as to the correctness of the diagnosis in this case, as the signs very strongly indicated disease of the superior maxillary bone, and as the roof of the mouth was not in any way affected. The result showed that the method sometimes used, of evacuating the sac and injecting a strong solution of carbolic acid or iodine would have proved futile. The question arises whether or not this tumor might be called a dentigerous cyst. Usually such a term is applied only to those cysts connected with the normal teeth. In the above case the sac was closely adherent to the abnormal tooth, and on extraction of the same quite a portion remained attached to the tooth.

—The French Ministry of Marine has decided that on and after January 1, 1890, wine furnished to the naval service must not contain more than thirty grains of sulphate of potassium to each quart.

PERISCOPE.

The Severe Vomiting of Pregnancy.

At the meeting of the American Gynecological Society, at Washington, Sept., 1888, Dr. Graily Hewitt, of London, in a paper with this title, said that the difference between the slight and severe vomiting of pregnancy is only one of degree. Many practitioners seem to be able to find no resource in these cases except the induction of premature labor. Severe vomiting may be due to several different causes. These may be classed as non-uterine and uterine. Among the reported fatal causes of the former class are disease of the stomach, liver, and intestines. Mathews Duncan has described a fatal case of "icterus gravis" during pregnancy; Lomer has recently written a paper on the same subject. The second class of causes are due to abnormal conditions of the uterus—such as anteversions and retroversions or flexions, induration of the cervix, and endometritis. Retroflexion of the gravid uterus does not always cause severe vomiting. On the other hand, retroflexion of the non-gravid uterus sometimes gives rise to vomiting. Several cases of impaction of the anteflexed gravid uterus have been reported; this impaction is due to the unyielding character of the uterine tissue. By dilating the cervix in cases of vomiting we overcome the tension in the neighborhood of the os internum. As regards treatment, most cases are cured by reducing the displacement, or sometimes by simply supporting the uterus. Severe vomiting may be of reflex origin, due to distension of the uterus. Some observers think that the nerves around the os internum are primarily irritated. There is a close parallel between cases of vomiting in flexions of the gravid and of the non-gravid uterus.

Dr. Fordyce Barker, of New York, said that the subject of the paper was one of great interest, and that the profession was already deeply indebted to Dr. Hewitt for former papers on it. The speaker believes that vomiting during pregnancy is largely influenced by the constitution of the patient. Some individuals can not even ride in a railroad car without feeling nauseated, while others are never affected. It is not strange that a constitutional tendency of this nature is apt to be exaggerated during the period of gestation when there is such a total change in the system. He does not believe that anteflexion of the uterus is a potent factor in causing vomiting, and he cited, in support of this opinion, a case of marked anteflexion in which the patient became pregnant and passed through the entire period without experiencing the least nausea. The flexion was not cured by gestation, but recurred after delivery. In another case there was marked retroflexion with absence of vomiting. However, he has seen cases in which vomiting was associated with flexions. He has seen in consultation no less than ten patients who were *in extremis* from severe vomiting, the question of inducing labor having been entertained too late. He has never been obliged to induce labor for this cause, having succeeded in curing the patients without it. There are many methods of treatment, some of them apparently contradictory. Sometimes it is wisest to give the patient what she craves most, as in a case in which he allowed a woman, who had been able to retain nothing whatever, to eat lobster salad, for which she had a longing. The speaker referred to Copeman's method of dilating the cervix, which he had frequently found of value.

Hemorrhage from the Bowel in Typhoid Fever.

Dr. J. A. Lindsay, Physician to Belfast Royal Hospital, in a communication in the *Dublin Journal of Medical Science*, April, 1889, reports two cases of hemorrhage from the bowel occurring in typhoid fever.

In the first case the hemorrhage supervened upon a sharp case of typhoid fever, attended by severe diarrhœa and an unusually high and continuous range of temperature. The hemorrhage, he says, undoubtedly aggravated the case enormously, and death was for some days imminent. In the second case the hemorrhage probably resulted from the patient's continuing to go about and to partake of unsuitable food. It evidently aggravated a case that was already grave through neglect, and was the beginning of the end.

Dr. Lindsay has made an analysis of all the cases of typhoid fever which have occurred at the Royal Hospital during the past twelve months, and thinks the result will throw some light upon the frequency and gravity of intestinal hemorrhage. Including the two cases referred to, the cases number 30. Hemorrhage took place in six instances (20 per cent.), and in two it proved fatal. The remaining patients who had no hemorrhage—24 in number—all recovered. These figures, he remarks, are somewhat unusual. They show 30 cases

treated, with 2 deaths—a mortality-rate of less than 7 per cent. The mortality from typhoid fever varies considerably; but taking Ireland as a whole, he thinks it is certainly not less than 15 per cent. The death-rate at the Royal Hospital during the past year has, therefore, been rather less than half the average. This record, he says, becomes still more remarkable when it is noted that both fatal cases were instances of relapse, and that the patients did not come into hospital sooner than the ninth or tenth week. Intestinal hemorrhage occurred in 6 out of the 30 cases—a somewhat large proportion. Louis records 134 cases, with hemorrhage in 8 only, and Murchison calculates that it occurs to an appreciable extent only in from 3 to 4 per cent. of cases. All Dr. Lindsay's cases in which hemorrhage occurred were of unusual severity. Of the six, two patients died, two recovered after hope had been almost abandoned, and the remaining two had very sharp attacks. These facts show (as far as they go) that hemorrhage is a very serious symptom, that it is not infrequently fatal, but that the most desperate cases may rally and make a perfect recovery.

As to the class of cases in which hemorrhage occurred, and the stage of the attack, Dr. Lindsay states that his cases support Murchison's statement that hemorrhage is rare in childhood. The six cases were aged respectively 27, 34, 19, 29, 28, 26. Thus, the average age at which hemorrhage occurred was 27, while the average age of the 24 cases in which there was no hemorrhage was 18½ years. As regards the period at which the hemorrhage occurred, the earliest was on the fourteenth day; in two others it occurred for the first time upon the nineteenth day, in a fourth case upon the twentieth day, and in the two remaining cases in the ninth or tenth week. It would appear that the later the hemorrhage the more serious the prognosis. Thus the four cases in which the hemorrhage occurred before the expiration of the third week all recovered, while in the two remaining cases in which it occurred in the ninth or tenth week both patients died.

With regard to his treatment of intestinal hemorrhage, Dr. Lindsay says he has always been accustomed to follow Murchison's instructions, and has given tannic acid, laudanum, and turpentine, with ice externally and ergotin by hypodermic injection. In one of his cases he gave laudanum pretty freely, in spite of the presence of albumin in the urine, and with good results—no sign of narcotism appearing. He is disposed to think that in intestinal hemorrhage, as in hematocele and other forms of internal bleeding, opium may be given fearlessly, and pushed even to heroic doses. Stimulants are certainly required in some cases, but must be regulated with much caution.

In conclusion, he says that, while intestinal hemorrhage in typhoid fever is a serious symptom, it is by no means usually fatal, and prompt and decisive treatment is called for, and will often prove effectual.

The Significance of a Fœtal Cardiac Rhythm.

M. Huchard has pointed out at the Paris Hospitals Medical Society (*La France Médicale*, No. 46) that the association of tachycardia (great rapidity of heart's beat) with equalization of the two silent periods and similarity of the two sounds is of more serious omen than simple tachycardia. It is found with weakening of cardiac contractility due to degeneration of the heart muscle and extreme lowering of arterial pressure from vascular paresis. Such a condition, therefore, is of grave augury, and the therapeutic indications are to restore the contractile power of the heart by hypodermic injections of caffeine, and that of the vessels by ergotin. He suggests the term "embryocardia," as descriptive of the condition that recalls the rhythm of the fœtal heart. In the discussion, M. Labbé demurred to the term, and expressed surprise at the results obtained by caffeine, doubting if it was absorbed, and fearing that it might be injurious in the large doses proposed by M. Huchard. M. Hallopeau thought the diminution of arterial pressure to be the result of the cardiac enfeeblement, and that cardiac rather than vascular tonics were indicated. Ergot of rye is a cardiac tonic. M. Huchard, in reply, said that he employed the term "embryocardia" because it is short and expressive. He asserts that it is safer to give caffeine (in the amount necessary in such cases) subcutaneously than by the mouth, and said the local inconveniencies at the seat of a hypodermic puncture can not be counted as against the relief afforded to the grave symptoms of the condition in which he employed it (M. Huchard's prescription was fifteen to thirty grains daily, in from four to ten hypodermic injections). Ergot of rye, he said, acts primarily upon the arterial system, and secondarily on the heart. —*Lancet*, April 27, 1889.

Mr. Stanley on Arrow Poison.

The *Lancet*, April 13, 1889, says that the letter from Mr. H. M. Stanley, which was read at a recent meeting of the Royal Geographical Society, contained an extremely interesting reference to the arrow poison employed by the natives of the Lower Congo district, and it afforded a curious insight into the strange perversions of knowledge by which the advances of civilization are retarded. Mr. Stanley says they were much exercised as to what might be the poison on the heads of the arrows by which Lieutenant Stairs and several others were wounded, and from the effects of which four persons died almost directly. The mystery was solved by finding at Arisibba several packets of dried red ants. The bodies of these insects were dried, ground into powder, cooked in palm oil, and smeared on the points of arrows. It is well known that formic acid exists in the free state in red ants, as well as in stinging nettles, and in several species of caterpillars. This acid is, in the pure state, so corrosive that it produces blisters on the skin, and hence there is little ground for doubting that it was the "deadly irritant by which so many men had been lost with such terrible suffering." The multitude of curious insects encountered, which rendered their lives "as miserable as they could well be," bears out Mr. Stanley's idea that many similar poisons can be prepared from insects.

The Bacteriology of Tetanus.

Professor Bizzozero has just submitted to the Royal Medical Academy of Turin the results obtained by Professor Tizzoni, of Bologna, and Signora Giuseppina Cattani on the bacillus tetani. These investigators took their material from a patient in the surgical wards, the victim of a fracture the seat of which had been contaminated by soil from the ground on which he had fallen. Traumatic tetanus of the most characteristic kind had ensued. Experiments made with the living blood in great quantity, with the median nerve and medulla of the bone taken a little above the point of fracture immediately after amputation of the limb, and also with the brain and spleen after death, yielded negative results, both with the cultures and the experiments themselves. From the material taken from the osseous surfaces of the fracture and from the soft parts immediately contiguous, there were obtained other microörganisms and the "bacilli spilliformes" of Nicolaier. These latter, inoculated in animals, produced tetanus, followed by death after twenty-four or forty hours. Left to themselves for three months in blood serum slightly solidified at a low temperature, there was again obtained from their inoculation distinct tetanus. Cultures of this liquid yielded a coccus, a short bacillus, and the bacillus of Nicolaier. Such colonies become so intimately fused with others that not seldom the transplantings from them turn out impure. This result probably accounts for the findings of Drs. Belfanti and Pescarolo. In any case Drs. Tizzoni and Cattani are the first, according to Professor Bizzozero, who have obtained a pure culture of the bacillus tetani, and who have kept it such throughout successive transplantings. The sequel of their researches will be awaited with special interest.—*Lancet*, April 20, 1889.

Professor Kremianski on Tubercle Bacilli.

Professor Kremianski, of Kharkoff, whose name is known in connection with the so-called aniline treatment of phthisis, has just published, in conjunction with Dr. Tseslinski, an article in the *Meditsinskoĕ Obozrênie*, or the importance of frequent microscopical examination of the sputum both for diagnostic and for therapeutic purposes, in cases in which phthisis is or may be present. The patients examined amounted to 931, and they were most of them seen in Professor Kremianski's polyclinic or out-patient department, something like 10,000 microscopical observations having been made during the course of the last two years. In addition, very thorough physical examinations were carried out, not merely by means of the stethoscope, but with the help of the spirometer, manometer, thoracometer, thermometer, and weighing machine. As far as possible, too, very complete notes were taken of the effects of different remedies. Of the 931 cases, tubercle bacilli were found in 570, or in 61 per cent., including cases of the most diverse description, some having cavities, some apex consolidation, and some merely signs of bronchitis or broncho-pleuritis. Thus, of the 570 cases presenting bacilli 220 patients, or 38 per cent., had cavities; 229, or 40 per cent., had apex consolidation; 19, or 3 per cent., had simple "bronchitis"; and 5, or 0.8 per cent., had "broncho-pleuritis." A considerable number (97) of the cases were sent by medical men to have the sputum examined for the

purpose of diagnosis. It was by no means uncommon to find a complete absence of bacilli in the sputum of patients presenting the clearest physical signs of phthisis—consolidation and even cavities. Of 238 patients with cavities, bacilli were absent in 18, or in 7 per cent. Of 419 cases of consolidation, bacilli were absent in 190, or in 45 per cent. Of 54 cases of "bronchitis" they were only absent in 35, or in 65 per cent. Bacilli were never found in cases of uncomplicated emphysema—*i.e.*, where there were no cavities or consolidation in addition. With regard to Professor Kremianski's special method of treatment, while it was only successful in entirely arresting the development of bacilli in about 30 cases, it produced a cessation of the ordinary symptoms of phthisis—cough, debility, fever, sweats, etc.—in about 300 cases.—*Lancet*, April 27, 1889.

Incurability of Syphilis.

Dr. W. R. Gowers, in the concluding Lettsomian lecture upon syphilis and the nervous system (*British Med. Journal*, Feb. 16, 1889) says: "I believe it is literally correct to say that we have no evidence that syphilis ever is, or ever has been, cured." Again he says: "The conclusion that the essential element in the disease resists treatment, and runs its course uninfluenced by our efforts, is in harmony with what we know of other specific diseases due to a poison introduced from without, and communicable from one person to another. There is not any fact whatever to show that a single disease of this kind can be cut short. The course of the acute exanthemata cannot be arrested by any means at our disposal at any stage of their course, and the same seems true of this chronic exanthematous disease. This is eminently true, also, of the disease that stands perhaps nearer to syphilis than any other known malady—leprosy."

With regard to the methods of administration of mercury, he says: "The old method of inunction seems to me to bring the patient under the influence of the drug as speedily as it can be done with safety, and with a certainty incomparably greater than the administration by the mouth. I have been deterred from a trial by the hypodermic method because the published evidence seemed to me not to afford any satisfactory proof of superiority, being destitute of the element of comparison essential to such proof, and because this method seems to afford an opportunity for psychical influence not free from risk of that which is undesirable. But I would not for one moment suggest that such an influence has entered into the motives or action of those who have used this method." Dr. Gowers believes that full doses of mercury and iodide of potash for from six to ten weeks will effect all that can be achieved in the removal of the syphilitic process. They should be continued only a little longer than is necessary to remove the lesion, being repeated, it may be, after an interval occupied by tonic treatment or by the other of the two chief drugs.

With reference to the consequences of the belief in the incurability of syphilis, he says: "If it is true that we cannot cure syphilis, it is most important to consider how it can best be kept in check. This is why the fact of incurability, if true, is so important. A mistaken belief in curability may dangerously hinder attempts at prevention. If no present treatment can prevent future developments, then it is wise, whether these come or not, to anticipate them. I think a custom, sometimes recommended, is prudent, that every syphilitic subject, for at least five years after the date of his last symptoms, should have a three weeks' course of treatment twice every year, taking, for that time, twenty or thirty grains of iodide a day. If this practice were adopted generally, is it not reasonable to anticipate grave lesions would be much more rare?"

Ectopic Testicle.

Charles Monod and G. Arthaud (*Archiv Gén. de Méd.*, Dec., 1887, say: Ectopic testicle is almost always accompanied by a progressive atrophy of the gland. Three stages of this condition are to be discriminated: 1. The spermatic function may still be preserved. 2. With preservation of the function, perivascular sclerosis and induration of the corpus Highmorianum occur, restraining secretions and producing sterility without atrophy. 3. Finally, atrophy of the gland occurs through connective tissue hypertrophy and disappearance of the epithelium.

They sum up as follows: 1. In almost all cases of ectopic testicle the gland atrophies. 2. No disturbance of function occurs in the beginning; later on, gradual impairment of function occurs. 3. Under the influence of external injuries and age, mechanical restraints to secretion and sterility develop. 4. Progressive sclerosis imparts to the ectopic testicle the conditions of senility.—*Brooklyn Medical Journal*, May, 1889.

Splenectomy for Floating Spleen with Strangulated Pedicle.

Dr. Y. H. Bond communicates to the *Weekly Medical Review*, April 13, an account of a very rare case in which he had performed splenectomy to relieve grave symptoms caused by twisting of the afferent and efferent vessels of the spleen. The patient was a woman, of good health, who had had four healthy children at full term, with no miscarriage, and was five months' pregnant with her fifth child. The symptoms were acute abdominal pain, vomiting, constipation, meteorism, and there was a history of the existence for about four years of a small, hard, movable tumor, about the size of a lemon, in the right iliac fossa. When admitted to hospital the patient was almost in collapse. Exploratory laparotomy was performed March 22, and the condition of the spleen already mentioned was found. The spleen when removed weighed 48 ounces and was 5½ inches wide, 3½ inches thick and 8½ inches long.

The contents of the uterus were expelled early on the morning following the operation. The patient died March 24. The *post-mortem* examination does not seem to have disclosed anything abnormal except general peritonitis.

An Epidemic of Parotitis.

Demme communicates an account of an epidemic of parotitis to the *Wiener med.-chirurg. Centralb.*, vol. xxiv., No. 5. The parotitis of this epidemic was very contagious, and usually affected all children exposed to it except those who were protected by a former attack. The average period of incubation was 8 to 15 days, but one boy, who was brought to the ward from a district in which no cases of mumps had appeared, took the complaint in three days. The duration of the invasion stage was 36 to 52 hours; the symptoms were restlessness and loss of appetite in mild cases, but in severe cases there were intense headache, vomiting, alternate restlessness and somnolence, and even delirium and convulsions. The temperature of this stage was 100° to 101° in mild cases, and 101° to 104° or more in severe cases. The swelling of and around the gland sometimes developed very rapidly—in 4 to 24 hours; in other cases it was so slow that it reached its maximum only in from 5 to 8 days. As a rule, the hardness was limited to the swelling of the gland itself, the surrounding swelling being of an œdematous character. In the majority of instances both glands were affected, though not in an equal degree. In a limited number the submaxillary and sublingual glands were also involved. The secretion of saliva at the beginning and at the height of the disease, was in a few cases diminished. The lymphatic glands behind and below the jaw were nearly always enlarged, and in anæmic individuals this swelling persisted. The enlargement of the parotid lasted usually from 8 to 14 days. The youngest patient was only 3 weeks old, but the commonest age was from 3 to 7 years. The cases occurred between June 1887 and May 1888, and their total number was 117. Eight were of a severe character, two ending in suppuration of the parotid, while two patients developed acute nephritis, and one suppurating otitis media. Two patients, a boy, three and a half years old, and a girl 7 years old, died in consequence of gangrene setting in. The course was much the same in both cases. When the parotid swelling was at its height a dirty greenish-brown vesicle appeared on the skin; this and its dark blue areola rapidly increased in size and soon developed into an ulcer with a dirty offensive discharge. Progress was very rapid. In the boy, 16 days after the appearance of the vesicle, almost the whole of the parotid gland was eaten away, and the nerves and blood-vessels dissected out. In the girl, the course of the gangrene was not quite so rapid, but there was no other essential difference between them. The gangrene was accompanied by extreme prostration, somnolence, cyanosis, cold extremities, epistaxis, and diarrhœa. The temperature gradually became subnormal.—*London Medical Recorder*, April, 1889.

Harmlessness of Saccharin.

The *London Medical Recorder*, April, 1889, says, with reference to the generally current idea that the use of saccharin is injurious, the following report has been published by Dr. Thomas Stevenson, official analyst of the Home Office:—1. Saccharin is quite innocuous when taken in quantities largely exceeding what would be taken in any ordinary dietary. 2. Saccharin does not interfere with or impede the digestive processes when taken in any practicable quantity. 3. His personal experience is that saccharin may be taken for an extended period without interfering with the digestive and other bodily functions; hence there is no reason to think that its continued use is in any way harmful.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Physician's Daily Pocket Record, - - 1.00
Reporter and Pocket Record, - - - - 6.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

A NEW TREATMENT FOR CHRONIC RINGWORM OF THE SCALP.

Only those who have attempted to cure a group of cases of chronic ringworm of the scalp can appreciate the disheartening obstinacy of the affection. Ringworm of the body is easily cured by a few applications of tincture of iodine, and so usually is ringworm of the scalp, when treatment is begun soon after infection has occurred. But when the fungus has once penetrated into the interior of the hairs and hair follicles it is sometimes almost impossible to eradicate it, and the longer the affection has lasted in any case, the more rebellious to treatment does it become. The fungus, so far as we know, does not cease to be susceptible to parasiticides, but the reason why the latter are so slow in acting is that they can not be brought into contact with the fungus, situated as it is deeply beneath the surface of the scalp. One of the most useful suggestions that has hitherto been made, with the view of obviating this difficulty, is that of Mr. A. J. Harrison, of Bristol, England. The results obtained in Philadelphia by the application of Mr. Harrison's method were communicated to the REPORTER, June 23, 1887, in an article by Dr. Herman B. Allyn. Without rehearsing Mr. Harrison's method, suffice it to say, that he employed a solution of caustic potash to soften the hairs and scalp tissues, and when this end was reached, the parasiticide was applied. Two solutions were thus used.

In a communication published in the *British Medical Journal*, March 2, 1889, Mr. Harrison gives what he believes, after considerable experiment and an experience with one hundred cases in two years, is an improvement upon that which has itself produced most excellent results. The author combines the remedies in an ointment composed of: caustic potash, nine grains; carbolic acid, twenty-four grains; lanolin and cocoanut oil, of each one-half an ounce. This ointment may be scented with some suitable oil, and a small portion of it should be rubbed into the affected parts night and morning. The caustic potash contained in it acts upon and softens the hair-matter, and in this way allows the carbolic acid to have free access to the fungus and its hosts of spores. The author thinks there is a decided advantage in leaving, when it can be done, as much as a quarter of an inch of hair; the ointment seems to have better play, and is kept on the part affected.

Those who have tried Mr. Harrison's former plan of treatment will receive his latest suggestion on the subject with great confidence, and will also be glad to learn that shaving of the head and still more, epilation, which is painful to the little

patient and extremely trying to the perseverance of the physician, are both unnecessary and even unadvisable. Carbolic acid is, of course, the parasiticide, and as it is not really an acid, there is, of course, no impropriety in combining it with an alkali.

Ringworm of the scalp is such a dreadful scourge that it may be worth while to mention in this connection the means employed by Mr. Harrison to prevent infection. He applies to the heads of children liable to be infected, an ointment composed of boracic acid and oil of eucalyptus, of each two ounces; oil of cloves, one-half a fluid drachm; and oil of cocoa-nut, sufficient to make six ounces. This makes an elegant prophylactic pomade.

TREATMENT OF CANCER BY ELECTRICITY.

The idea of attempting to limit the advance of malignant growths by means of electricity is not a new one. From time to time powerful electrical currents have been passed through morbid structures, in the hope that their physiological or pathological functions would be so altered thereby as to lead to their disappearance. Thus far these attempts have never led to any great success. Very recently, however, Dr. J. Inglis Parsons, of the Chelsea Hospital, London, has made some new experiments in this direction, and has reported their results in the *British Med. Journal*, April 27, 1889. In this report, which is characterized by a tone which, under the circumstances, is remarkably temperate, Dr. Parsons gives an account of the histories of four cases, in which he applied the Voltaic current, as high as 600 *milliampères*, at intervals, with what he believes to have been an effect calculated to encourage the profession to a further trial of this agent for the treatment of cancer.

It would be a good thing, if the hopes suggested by Dr. Parsons could be realized. But, unfortunately, we see little in his report to warrant them. Although he himself does not press any claim to the establishment of a method of treatment, and reports his cases in a manner wholly free from exaggeration or over confidence, still they must not be taken without careful and critical investigation. When these are applied to them, we find that they are not of a character to justify any positive conclusions in regard to the influence of electricity upon cancer. This, because some of the four cases are of doubtful diagnosis, and in some the evidence of improvement is so slight that it requires a decided bias to believe that there was anything in them different from what is often observed in others in which there is no treatment at all, and which eventually end in death.

The theoretical explanation of the influence of the Voltaic current on cancer cells offered by Dr. Parsons is interesting; but it must not be overlooked that it is altogether theoretical, and that it is so far entirely unsupported by any reliable observation.

We have devoted this much space to the matter under discussion, because there are some things in the report which are calculated to incline the reader very favorably to whatever the writer may advocate, and there seems to be some danger that this inclination may lead to too ready an acceptance of a very attractive and tempting hypothesis, which is as yet utterly an hypothesis.

FLUORINE AS A REMEDIAL AGENT.

In addition to the Editorial on fluorine in the REPORTER, Jan. 12, 1889, it will doubtless interest our readers to know that Dr. Ludwig Polyák, of Görbersdorf, has recently made a careful study of the evidence in regard to the effect of inhalations of hydrofluoric acid in phthisis, and concludes that, so far from being of value, they are absolutely injurious.

His report is contained in the *Wiener med. Presse*, Nos. 6 and 7, 1889, and is of the most conclusive sort. It seems clear, on reading it, that nothing as yet points to a method of utilizing the properties of this important chemical agent in the treatment of pulmonary phthisis.

PATHOLOGICAL ANATOMY OF ESSENTIAL EPILEPSY.

The exact pathological anatomy of idiopathic or essential epilepsy is still very obscure, so that some recent statements by M. Chaslin before the Biological Society of Paris, at its meeting on March 2, are interesting and may perhaps throw new light on the subject. According to the *Bulletin Médical*, March 6, 1889, M. Chaslin has had occasion to study the brains of several epileptics, and his study has led him to the conclusion that certain lesions, described under the name "cerebral sclerosis," are due to a proliferation of the cells of the neurolgia. He proposes for this process the name "neuroglic sclerosis." Further, he believes the induration at certain points, especially in the horns of the hippocampi majores or in the olivary bodies—which has been long noted in cases of epilepsy—is the external sign of the hidden proliferation of the neuroglia.

According to this view, idiopathic epilepsy would in some cases be due to an excess of development of the connective tissue of the nerve fibres, which Chaslin thinks should be attributed to a lesion received during embryonic life.

IDLENESS AND INSANITY.

The enforced idleness of the male prisoners in the State's prisons of New York, brought about by "the friends of labor," has proved a great misfortune to the convicts. Labor is just as essential to their well-being as it is to that of the citizen at large, if not more so. The increase of sickness, and especially of insanity, has been very marked since their regular employment was legislated away from them. The wardens have noticed, and reported, a falling off in their physical strength, while the medical attendants have found mental derangement and sexual perversion result from the idleness and solitary confinement. One of the surgeons resigned lately, and took occasion to express his conviction that a condition of misery would soon follow with which he would be powerless to cope; that, whereas formerly few of the convicts became sick, and rarely did one go insane, lately the hospital has been kept full, and as many as two and three have become fit subjects for transfer to the State asylums. Furthermore, as the prisoners are almost constantly going crazy and becoming more or less violent, in consequence, the danger to the physicians, attendants and their fellow prisoners was vastly increased.

CONSOLIDATION OF MEDICAL JOURNALS.

One of the most interesting signs of the times is to be found in the practical application of the belief that there are in this country altogether too many medical journals. One who is in a position to see how many useless and relatively worthless medical journals start into existence, from time to time, finds it not unnatural to regard with a sense of satisfaction the high rate of mortality that prevails among them. On the other hand, many journals which have already obtained a certain recognition by the profession, though unworthy representatives, from time to time succumb. In addition to this—a much more rare occurrence—once in a while worthy periodicals, which have existed as rivals in the same field, come together as allies, and continue the work which they have begun, with united force and with improved prospects of success.

An occasion of the latter kind is found in the combination of the *Medical Press of Western New York*, and the *Buffalo Medical and Surgical Journal*. The number of the *Medical Press* for June, 1889, contains an exceedingly interesting valedictory editorial, in which Dr. Roswell Parke explains the excellent reasons for which the combination has been made. The result of this combination cannot, we think, fail to be advantageous to the medical profession of Western New York, which has already been ably represented in the two journals, but which must be better represented when all appear-

ances of rivalry between them have disappeared.

The high character of both of these periodicals has always made them welcome visitors to the tables of their contemporaries, and it is a great satisfaction to know that their excellent qualities will hereafter be united in one journal which must be stronger and better than either could be alone.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

THE PSYCHIC LIFE OF MICRO-ORGANISMS. A STUDY IN EXPERIMENTAL PSYCHOLOGY. By Alfred Binet. Translated from the French by Thomas McCormack. Small 8vo, pp. xii, 121. Chicago: Open Court Publishing Company, 1889. Price, 75 cents.

This is one of the most interesting books which have come to our table for a long time. The author traces the manifestation of mental activity down into the very lowest forms of animal, and even to those of vegetable life. As an illustration, he says of the hunter Infusoria, that they are constantly running about in quest of prey; but this constant pursuit is not directed toward one object any more than another. They move rapidly hither and thither, changing their direction every moment, with the part of the body bearing the battery of trichocysts held in advance. When chance has brought them in contact with a victim, they let fly their darts and crush it; at this point of the action they go through certain manœuvres that are prompted by a guiding will. It very seldom happens that the shattered victim remains motionless after direct collision with the mouth of its assailant. The hunter, accordingly, slowly makes his way about the scene of action, turning both right and left in search of his lifeless prey. This search lasts a minute at the most, after which, if not successful in finding his victim, he starts off once more to the chase and resumes his irregular and roving course.

In like manner the author discusses a variety of phenomena which indicate purposive actions in protozoans and microphytes. His book is admirably conceived, and excellently written, and cannot fail to interest those who have any inclination to study the powers and possibilities of beings below us in the scale of life.

Literary Notes.

—The *Weekly Medical Review*, of St. Louis, Mo., announces that beginning with the first issue in July it will appear in a new dress, and be enlarged to the size of the *New York Medical Journal*. The subscription price will remain unchanged.

—William Blaikie, author of "How to Get Strong, and How to Stay So," and "Sound Bodies for our Boys and Girls," will write, in *Harper's Magazine* for July, upon the question: "Is American Stamina Declining?" and will make a number of practical suggestions for reforming our system of education in the direction of physical training.

Notes and Comments.

The Purification of Sewage.

Science, April 12, 1889, says the plan proposed by Mr. W. Webster, for the purification of sewage by electrolytic methods, has been tried on a large scale, and with encouraging results. The process is very simple, and is described by the *London Electrician* as follows: "The color, density, and constitution of the London sewage varies from hour to hour in the most extraordinary manner; but the first sample to be dealt with was of a light-yellow color, looking something like weak tea with a little milk in it, but, so far as could be seen, it contained very little solid matter in mechanical suspension. This having been poured into a test-jar, a current was passed through it between a pair of iron electrodes, with about six volts electro-motive force. An extremely rapid effect was produced. In less than two minutes the jar was seen to be filled with a flocculent precipitate, which was gradually carried upward by the bubbles of liberated hydrogen. After about three minutes, the electrodes were withdrawn, and the precipitate left to collect at the top. In actual practice, after the effluent has passed into the settling-tank, the precipitate, in the course of about two hours, loses the whole of the entangled hydrogen; it then sinks to the bottom of the tank. The sludge thus formed is similar to that produced by the chemical processes now in use, except that the electrical method possesses the obvious advantage that the total quantity of material has not been increased by the addition of chemicals." But, besides this precipitation, there is an action on the organic matters in solution which robs them of their unpleasant and harmful properties. In the larger experiments, carried on at Crossness, two 20-horse-power engines are used, with an Edison-Hopkinson dynamo. Iron plates are placed in the shoot through which the sewage is discharged. In travelling along the shoot, every particle of the sewage comes in contact with the plates, and finally the whole is received into the settling-tanks. With 27 horse-power, it is possible to treat a million gallons of sewage in twenty-four hours. The consumption of iron in actual working is about two grains per gallon. Taking a town with a daily flow of ten million gallons of sewage a day—corresponding to a population of about 300,000—the consumption of iron should not exceed 304 tons per annum,

and the steam-plant required would be about 250. This plant takes the place of the mixing-tanks, machinery, and chemicals employed in the chemical process for the purification of sewage; and, if such electrical plant is designed to meet the peculiar requirements of the district, it should cost less than any other method, besides precipitating and purifying in one operation.

Bicarbonate of Sodium and Bichloride of Mercury in the Treatment of Yellow Fever.

In the *Therapeutic Gazette*, August 15, 1888, Dr. George M. Sternberg suggested the use of bicarbonate of sodium and bichloride of mercury in the treatment of yellow fever. At Decatur, Florida, in the following October, the yellow fever prevailing was of a most malignant type: of 10 physicians practising in the infected area, 9 had yellow fever and 5 died. The treatment referred to was then tried. In the *Gazette* for May 15, 1889, Dr. Sternberg states that 32 white and 32 colored patients were subjected to the treatment by four physicians; of this number, only 4 died—all white. Dr. Mitchell writes from Jacksonville that he treated in all 216 cases of yellow fever, and that the mercury and soda gave the best results. As the result of experience with the bichloride and alkaline treatment, Dr. Sternberg suggests for further trial the following formula, which is a modification of the one first suggested:

Sodii bicarb. . . . . ℥iv
Hydrarg. chlor. corros. . . . gr. ss
Aquæ puræ . . . . . Oii
M. Sig. One and three-fourths ounces every hour; to be given *ice cold.*

Important Notice to the Medical Profession.

The Department of the Interior, Census Office, at Washington, has just issued a circular calling attention to the fact that Dr. John S. Billings, Surgeon U. S. Army, has consented to take charge of the Report on the Mortality and Vital Statistics of the United States as returned by the Eleventh Census.

As the United States has no system of registration of vital statistics, such as is relied upon by other civilized nations for the purpose of ascertaining the actual movement of population, our census affords the only opportunity of obtaining even an approximate estimate of the birth and death rates of much the larger part of the country, which is entirely unprovided with any satisfactory system of State and municipal registration.

In view of this, the Census Office, during the month of May, 1889, will issue to the medical profession throughout the country "Physician's Registers" for the purpose of obtaining more accurate returns of deaths than it is possible for the enumerators to make. It is earnestly hoped that physicians in every part of the country will co-operate with the Census Office in this important work. The record should be kept *from June 1, 1889, to May 31, 1890.* Nearly 26,000 of these registration books were filled up and returned to the office in 1880, and nearly all of them were used for statistical purposes. It is hoped that double this number will be obtained for the Eleventh Census.

Physicians not receiving Registers can obtain them by sending their names and addresses to the "*Census* Office," Washington, D. C., and, with the Register, an official envelope which requires no stamp will be provided for their return to Washington.

If all medical and surgical practitioners throughout the country will lend their aid, the mortality and vital statistics of the Eleventh Census will be more comprehensive and complete than they have ever been. Every physician should take a personal pride in having this report as full and accurate as it is possible to make it. It is promised that all information obtained through this source shall be held strictly confidential.

Quinine Rash.

At the meeting of the Clinical Society of London, March 8, 1889, Dr. Burney Yeo gave an account of several attacks of a quinine rash which he had personally experienced. The first attack occurred in August, 1887, while he was taking two grains of quinine three times a day for a cold in the head; the second about two months afterward, when taking quinine in the same doses for the same purpose; the third, in Rome, in January, 1888, after a single dose of three grains. The true nature of the eruption was not suspected in the first attack, and doubted in the second, as the author had repeatedly taken quinine during former attacks of coryza without any such manifestations. Thinking there might be some impurity in the quinine, the author in May last obtained a different sample, the purity of which was vouched for, and, after taking two doses of three grains each, the rash shortly made its appearance as before.

Some time afterward he again tested himself by a very small dose, hoping thereby to establish a tolerance of the drug, but a single dose of a quarter of a grain was rapidly followed by precisely the same cutaneous manifestations. The eruption, which the author fully described, assumed the same character and distribution on each occasion, and was of an erythematous nature, in patches of various sizes and forms, most of them a little raised above the surface. A remarkable fact was that on every occasion it was strictly limited to the lower extremities, extending up to the groins, but never passing beyond that limit. There was no constitutional disturbance. The author having referred briefly to the history of quinine rashes, concluded the paper with some interesting reflections and inferences on the remarkable fact that a drug which had been for years, and quite recently, perfectly tolerated, should suddenly in the same person cause such decided cutaneous disorder, and in such minute doses. In answer to a question by Dr. Powell, whether any actual febrile phenomena attended the rash, Dr. Yeo stated that no febrile phenomena had accompanied the appearance of the rash; and that he had experienced no other symptoms of quinine poisoning, and no tenderness of the skin. The eruption was disagreeable at night. He mentioned a case in which similar symptoms had followed the ingestion of a dose of salicylate of soda. He pointed out that the effects of quinine varied very much according to the form in which it was given. When given in the solid form it sometimes proved unsuccessful, while it gave excellent results when administered in the form of an effervescing draught.—*British Med. Journal*, March 16, 1889.

Ice-bags in the Night-Sweats of Phthisis.

Prof. Rosenbach, of Breslau, recommends in the *Berliner klin. Wochenschrift*, No. 15, 1889, the use of ice-bags for the night-sweats of phthisical patients. These bags, moderately filled, are laid during several hours of the night upon the abdomens of the patients. This remedy, he says, is generally well borne, especially by those patients who have a rise of temperature in the evening, and is of service in many cases in which atropine and the dusting of the body with powdered salicylic acid have failed. The bags, he says, can be used for many nights without harm to the patient.

Execution by Electricity.

The Philadelphia *Evening Telegraph*, June 10, says: The appeal made by Kemmler's counsel from the decision of the Buffalo Courts, on the ground that electric execution is "cruel and unusual," will be supported by many electricians of this city, some of whom, it was rumored to-day, are so opposed to the new method of execution that they have opened their purses to pay counsel fees to the condemned man's lawyers. A large number of electricians were interviewed this morning on the main feature of the appeal, namely, that "electrocution is cruel." Every one of them said that the new method is not only cruel, but extremely uncertain. Ralph W. Pope, Secretary of the American Institute of Electrical Engineers, said: "This killing by electricity will prove to be more cruel than hanging, shooting, beheading, or any modern civilized method of execution, because it is the most uncertain, and the criminal must undergo more protracted mental agony during the preparations. We do not know yet just what amount of electricity will kill a subject. Different individuals have different powers of resistance, and not only that, but the power of resistance in the same man may vary very greatly within half an hour or less. Take Kemmler, for instance. A half hour before turning on the presumably fatal current he is 'tested.' There is no assurance of the correctness of this test.

"Of course the sure method would be to apply tremendous pressure, 5,000 volts or more. But then it is extremely possible that the body would be horribly mutilated in that case. It is not difficult to imagine the preliminary sufferings of the man. He must sit in the chair in an agony of expectation, while the executioner and his assistants are running about for an hour or more preparing the apparatus, he not knowing at what moment the current might be turned on; and then suppose, as may happen, that the shock should not prove fatal."

Creasote Pills.

In the *Gazette Hebdomadaire*, May 10, 1889, Dr. Charles Eloy gives the following formula for making creasote pills, which are useful especially when cough and diarrhœa exist:

Creasote	gr. xxx
Acetate of lead	gr. iv
Extract of opium	gr. iii
Syrup	
Gum arabic āā q.s. ad faciendas pil. No. c.	

Administration of Belladonna in Whooping-Cough.

Dr. Éloy writes in the *Gazette Hebdomadaire*, May 3, 1889, that belladonna may be administered during the catarrhal period, during the spasmodic stage, and in the decline of whooping-cough.

In the catarrhal period it is useful to combine with it other calmatives. Simon recommends the following formula:

Tincture of belladonna
Tincture of aconite root . . . . āā gtt. x
Cherry laurel water . . . . . f℥ iiss
Lime (fruit) water . . f℥ iii
Syrup of lettuce . . . . . f℥ i
M. Sig. Spoonful every three hours.

In the spasmodic stage, following Hufeland and Trousseau, Vienna physicians prescribe the powder of belladonna.

For small children, Bamberger gives morning and evening one of the following powders:

Powder of belladonna root . . . . gr. iss
White sugar . . . . . gr. lxxv
M. Div. in pulv. No. x.

To older children, Monti administers two or three times a day one of the following powders:

Belladonna root . . . . . gr. iss
Bicarbonate of soda
Pulverized white sugar . . . āā gr. xxiii
M. Div. in pulv. No. x.

Belladonna may also, as suggested by Monti, be combined in a powder with quinine, of which he gives two or three a day:

Powdered belladonna root . . . gr. iss
Sulphate of quinine . . . gr. viiss
Powdered white sugar . . . gr. xxx
M. Div. in pulv. No. x.

The tincture of belladonna may be administered pure—following the example of Bamberger and giving from two to fifteen drops a day, in three or four doses according to the age of the patient, watching the state of the pupil and for symptoms of poisoning—or in the following draught:

Tincture of belladonna . . . . gtt. ii–vi
Gum julep . . . . . f℥ ii
M. A coffeespoonful every two hours.

In the intense form, Ellis recommends extract of belladonna, and especially the following mixture:

Extract of belladonna . . . . . gr. $\frac{1}{6}$
Bromide of potash . . . . . gr. $\frac{5}{6}$
Syrup of poppy . . . . . gtt. xv
Water . . . . . ♏ lxxv
M. For one dose.

This dose is increased, if necessary, up to five-sixths of a grain of the extract a day, if it is well borne, watching closely the action of the remedy.

In the period of decline, it is still proper to prescribe belladonna, according to M. Simon, but in association with tonics—cod liver oil, iodide of iron, and quinine.

Some Abuses of Etherization.

In a paper on this subject in the New York *Medical Record*, Feb. 23, 1889, Dr. George F. Shrady recommends the following precautions in order to avoid many of the abuses of anæsthesia:

1. In commencing the administration of ether the gradual method is to be preferred.

2. Its employment allows the lungs to empty themselves of residual air, prevents coughing and struggling, and places the organs in the best possible condition to receive and rapidly utilize the ether vapor.

3. After the stage of primary anæsthesia is reached, the more pure ether vapor the patient breathes the better.

4. The shorter the time of anæsthesia, and the smaller the amount of ether used, the less likely are the unpleasant sequelæ to occur.

5. The more evenly it is administered the less shock to the patient.

6. Anæsthesia should be entrusted to experienced administrators only.

7. Many of the fashionable efforts to resuscitate patients are not only useless but harmful.

8. The minimum amount of force should be employed to restrain the muscular movements of the patient.

9. Mixed narcosis is often advisable for prolonged operations.

10. The utility of the galvanic battery, in threatened death, is yet to be proven.

11. The most trustworthy means of resuscitating desperate cases are artificial respiration, hypodermic stimulation, inhalation of nitrite of amyl, and inversion of the body.

Strophanthus for Dyspnœa.

Demme, according to the *Deutsche med. Wochenschrift*, April 11, 1889, has recommended the use of strophanthus in the case of children affected with dyspnœa in the course of chronic nephritis, in bronchial asthma, and in whooping cough, and also to obviate dropsy in conditions of low blood pressure. He gives three drops (of the tincture) four or five times a day, and says that as a rule strophanthus should not be given to children under five years of age.

Bichloride of Mercury in Anæmia.

Dr. A. M. Cartledge, Demonstrator of Anatomy in the Kentucky School of Medicine, contributes a paper on bichloride of mercury in anæmia to the *American Practitioner and News*, May 11, 1889. He believes mercury has the power of causing absorption of lymph deposits and of relieving glandular engorgement.

In the anæmia of women the subject of disease connected with the organs of generation, he says he knows of no one constitutional remedy the equal of mercury. Nearly all of these cases are the subject of lymph deposits and ovarian congestion, which is best met by an agent which so decidedly facilitates healthy gland action. In the chlorosis which is so often a manifestation of struma, he says the bichloride of mercury with iron will often effect a cure where iron alone fails. The great good mercury does, especially as calomel, in relieving acute glandular engorgement, is appreciated. What he thinks we need most to be impressed with is its great virtue in relieving those often obscure and chronic obstructions to gland action which exert so potent an influence for evil in the economy.

Treatment of Rheumatism.

At the meeting of the Clinical Society of London, April 16, 1889, Dr. W. N. Maccall read a paper upon the treatment of the various forms of rheumatism. After reviewing the previous treatment of acute rheumatism, during the last twenty-five years, Dr. Maccall considered the value of the present routine treatment by salicylic acid and its allies or derivatives under the following headings: 1. In relieving pain and lessening fever in acute rheumatism, the salicyl treatment is undoubtedly the most effective known. 2. The salicylates do not prevent the rare complication of hyperpyrexia, and are absolutely useless in its treatment. 3. It is doubtful if they prevent endocardial or pericardial troubles, the percentage remaining about the same (50 per cent.) since the salicyl treatment as before. They seem to have no influence in curing these troubles when they do occur. 4. There is no proof that the salicylates prevent relapse. 5. It is not proved that the salicylates lessen the duration of the disease, nor that they prevent anæmia. With regard to the particular form of the remedy, most writers recommend, and Dr. Maccall agrees with them, salicylate of soda in twenty-grain doses, at first every hour for three or four hours, according to circumstances. It should be continued in diminishing doses for at least eight or ten days after all pain and pyrexia have ceased, and in most cases should be followed by iron. Salicylic acid, salicin, and salol may be tried in exceptional cases where the soda salt is not well borne. In young children, antipyrin may be substituted with advantage. In convalescence, Sir A. Garrod's alkaline mixture followed by iron was recommended; and if any joint remain stiff or swollen, blistering or painting with iodine is useful.—*British Med. Journal*, May 4, 1889.

Abortive Treatment of Gonorrhœa after Cocaine Anæsthesia.

A member of the Society of Medicine and Pharmacy of Isère treats gonorrhœa in the following way (*Jour. de la Soc. de Méd. et de Phar. de l'Isère*, Dec., 1888): He first washes out the urethra with a large amount of aseptic water, and then fills it with a ten-per-cent. cocaine solution. After leaving this injection in for about five minutes it is allowed to escape, and what remains is washed out with more sterilized water.

The urethra now being anæsthetized, an aqueous solution of silver nitrate, of the strength of 1 to 25, is injected into the urethra as far as any inflammation is supposed to exist. This application, he says, neither produces nor is followed by any pain.

The complete removal of the cocaine solution is necessary, because of the incompatibility between the silver solution and the hydrochlorate.

As the discharge lessens, a sulphate of zinc solution, 1 to 500, is generally indicated.—*Medical Analectic*, February 21, 1889.

A Large Bill.

A New York paper states that the estate of a late eminent statesman and lawyer is about to be sued for a bill of medical attendance covering visits over 2,200 in number, the value of which is placed at $143,350. If the question of overdue interest does not enter into the account, the average value of these services would be about $65.10 per visit. During a part of the time, however, the physician was in constant attendance upon his illustrious patient, and there is a strong presumption that he will be able to prove his case and win his bill.

Salicylates in Pruritus Senilis.

In one of his recent lectures, according to the *Wiener med. Presse*, May 5, 1889, Besnier recommended the treatment of pruritus senilis with the salicylates. In addition to bran baths, Besnier recommends washing of the body every evening with water to which two tablespoonfuls of the following solution have been added:

Carbolic acid	ʒi
Aromatic vinegar	fʒvi

Then the following powder is dusted on:

Salicylate of bismuth	ʒv
Starch	℥ii ʒviss

or:

Finely powdered salicylic acid .	gr. cl
Starch	℥ii ʒviss

Treatment of Typhlitis.

Prof. Bouchard, according to the *Bulletin Médical*, April 24, 1889, says the indications are as follows: (1) to allay the pain; (2) to put the intestine at rest and reduce digestive fermentation to the minimum; (3) to ensure asepsis of the large intestine. The following are the proper procedures to fulfil these indications: 1. To allay pain, apply cataplasms, use mercurial and belladonna inunctions, and administer hypodermic injections of morphine. 2. For nourishment, use milk with an alkaline water or with the addition of yolk of egg; avoid solid or easily fermentible substances. As a laxative, to keep the intestine free, give a teaspoonful of magnesia in sweetened water, or a teaspoonful to a dessertspoonful of castor oil, avoiding violent purgatives. 3. To ensure asepsis of the intestines, wash out the large intestine twice a day with a quart of the following solution, heated to a temperature of 100° Fahr.:

Water	fʒxxx
Borate of soda	gr. lxxx
Tincture of benzoin, Camphorated alcohol	āā ♏ lxxx

Fatal Injury from Base-ball.

At Dundee, Indiana, two base-ball players came into violent collision, and one of them received injuries which were fatal. It has long been an opprobrium of the English game of foot-ball that so grave—even fatal—injuries frequently result from the misdirected energies of its players; and now to have the American game brought into the same category would be little short of a calamity. The game is universally popular, has much in its favor as an athletic pastime, and is deserving of being so regulated as to be made free from danger to life and limb.

NEWS.

—It is reported that yellow fever exists at Vera Cruz.

—The German Anatomical Society will hold its third meeting in Berlin early in October, 1889.

—Professor Virchow is reported to be engaged in rewriting his great work on Cellular Pathology.

—Prof. Wilhelm Bunsen has resigned his position as Professor of Chemistry in the University of Heidelberg.

—The New York *Medical Record*, June 8, 1889, says that a new case of leprosy is reported to be at the Harlem Hospital.

—The death is reported of Dr. R. Ultzmann, Extraordinary Professor of Diseases of the Urinary Organs in the University of Vienna.

—A man named Hughes, who visited the scene of the disaster at Armagh, Ireland, was so horrified at the sight that he died on the spot.

—Dr. John W. Pearce, of Oxford, Ala., died May 26, at the age of 62 years. He was graduated at the Georgia Medical College in 1857.

—Professor Breisky, of Vienna, the well-known obstetrician, died recently of carcinoma of the sigmoid flexure of the colon. He was fifty-seven years old.

—Dr. J. E. Kunkler, of San Francisco, died in that city May 10, of cancer of the throat. Dr. Kunkler was graduated from the University of the Pacific, now Cooper Medical College, in 1863.

—Professors Virchow, von Bergmann and Waldeyer, the committee entrusted with making arrangements for the International Medical Congress, which meets in Berlin next year, have already held a preliminary meeting.

—Dr. James F. Foulkes died in Oakland, California, May 22, 1889, of diabetes mellitus. Dr. Foulkes studied at Princeton College, New Jersey, and was graduated in medicine from the Jefferson Medical College, in 1852.

—Dr. Lindley, one of the Editors of the *Southern California Practitioner*, has been sued for $20,000 on account of alleged malpractice. The complaint states that in an obstetrical case (one of version) an assistant of the Doctor's, in moving the patient on the bed, dislocated her shoulder.

HUMOR.

"THERE IS SUCH A THING as carrying a choke too far," as a Colorado horse-thief remarked at a neck-tie social.—*Drake's Magazine.*

PROUD FATHER (showing off his boy before company)—"My son, which would you rather be, Shakespeare or Edison?"

Little Son (after meditation)—"I'd rather be Edison."

"Yes? Why?"

"'Cause he ain't dead."—*New York Weekly.*

PLAYWRIGHT—"It seems to me that if I had a better title for my drama it would have more success."

His Friend—"Call it 'Anti-Fat.'"

Playwright—"Why so?"

Friend—"I see it has reduced the audience more than one-half in less than an hour."—*Terre Haute Express.*

TO BUILD UP HIS SYSTEM.—Dr. Schmerz.—"The trouble, Mr. Tyers, is that you don't take enough exercise." Mr. E. Z. Tyers. "Aw, I confess I don't go in vewy heavy on athletics, doctaw. What could you wecommend as a mild exercise to begin on?" Dr. Schmerz. "H'm! You might stretch your arms over your head when you yawn!"—*Puck.*

OBITUARY.

JAMES ETHELBERT MORGAN, M.D.

Doctor J. E. Morgan, of Washington, D. C., died at his residence, on the morning of June 2, of Bright's disease. Dr. Morgan was born in St. Mary's County, Maryland, September 25, 1822. He was a descendant of the Morgan and the Cecil families of England. His collegiate education was received at St. John's College, Md. He was graduated in medicine at the Medical Department of the Columbian University, Washington, in 1845, and immediately entered into active practice. Shortly after graduation he was appointed Demonstrator and Assistant to the Professor of Anatomy in the University. In 1852, Dr. Morgan was selected as Professor of Physiology in the Medical Department of the University of Georgetown. This position he resigned in 1858, and, at the earnest solicitation of the Faculty, he accepted the chair of Materia Medica and Medical Jurisprudence, which he held until the re-organization of the Faculty in 1876, when, with Drs. Noble Young, Johnson Eliot and Flodoardo Howard, he retired from active participation in the College duties to become Emeritus Professor.

As a lecturer, Dr. Morgan was clear and forcible, and is affectionately remembered by the hundreds of students who graduated under his teachings. Among the official positions he has held may be mentioned, those of Physician to the Washington Asylum and Small-pox Hospital; member of the Board of Aldermen; member of the Board of Health of the District of Columbia; trustee of the Public Schools; Surgeon-in-charge of the Soldiers' Rest; Surgeon-in-Chief to the Quartermaster's Hospital, Washington, from 1861 to 1865. At the breaking out of the war he was appointed Colonel of the 4th Regiment, D. C. Vols. Dr. Morgan was a member of the Medical Association and of the Medical Society, D. C., and of the American Medical Association, having held various offices in each of them.

In 1854, he married Nora, the daughter of William Dudley Diggs, of Maryland, who, with six children, survives him.

Dr. Morgan's published papers are few, and consist for the most part of addresses before the College to which he was attached, and at the medical societies of which he was a member. He retired from active practice some time ago, but was very frequently sought in consultation, especially by the younger members of the profession, to whom he freely gave the results of his ripe experience. Dr. Morgan possessed a large frame and a vigorous constitution, and only a few weeks ago was apparently a well and hearty man.

His death adds another name to the already long list of losses which have befallen the medical profession of Washington. L. E.

JAMES B. HUNTER, M.D.

Dr. James B. Hunter, the well-known surgeon, died at his home in New York, June 10, after an illness of six weeks. Dr. Hunter occupied several prominent positions, having been Attending Surgeon to the Woman's Hospital, Surgeon to the New York Cancer Hospital, of which he was one of the founders, Consulting Surgeon to the New York Infirmary for Women and Children, and Professor of Diseases of Women at the New York Polyclinic. He was a member of various medical societies, and made numerous valuable contributions to current medical literature.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

REPORT OF A CASE OF STRICTURE OF THE RECTUM, THE PROBABLE RESULT OF A SPECIFIC VAGINITIS.

BY LEWIS H. ADLER, JR., M.D.,
LATE RESIDENT PHYSICIAN, UNIVERSITY HOSPITAL, PHILADELPHIA, PENNA.

The usual causes of stricture of the rectum—when not carcinomatous in nature—are: syphilitic infection; traumatism, in the shape of the introduction of foreign bodies; the careless use of clyster-pipes; and the various operations upon the mucous coat of the bowel, as well as any inflammation or ulceration arising in other ways. *Both gonorrhœal* and *leucorrhœal* discharges may become potent factors in producing this painful affection. Such was the only assignable cause of the stricture in the following case, which I wish to record:—

Mrs. S. H. M.; aet 27; white; a widow, whose occupation was that of a housekeeper, was admitted into the University Hospital in November, 1888, suffering, as she stated, with a lacerated perineum and some rectal trouble, which gave her intense pain every time she had a movement of the bowel. Her family history was good, and showed no evidence of malignant disease, either of the rectum or elsewhere. As a child, she had the various diseases of childhood; otherwise she was healthy. She first menstruated at 13, and was always regular—she was married at 16, and two years later left her husband, owing to family trouble. Two children were the result of this union. The last child was born in the early part of 1879. Both labors were difficult. Instruments were resorted to in the delivery of the first child. Both children presented by the head. It was in the first labor that she was torn, and she thinks the tear was increased at the birth of the last child.

She suffered more or less from this trouble, owing to the loss of control over the contents of the bowels; but by means of anodynes and careful diet she managed to keep costive. Every two or three weeks she would take an aperient. She was advised to have an operation performed, but refused. Such was her condition up to three years before her admittance into the hospital, under the care of Professor Wm. Goodell.

Her present trouble began in 1885. At the solicitation of a man in the town in which she lived, she had sexual intercourse

with him, which resulted in a violent attack of specific vaginitis. Not long after this trouble began, the movements of her bowels caused more pain than ever—so much so, that the thought of going to stool would drive her wild with fear. Instead of resorting now to anodynes, and a diet that would produce hardened feces, she did all in her power to render them easy of passage.

She grew steadily worse, and, though advised to come to the city and undergo an operation, she steadfastly refused. Her stools were now typical of stricture of the rectum. It was not until the end of 1888, when life had become more than a burden, that she consented to come to the city and have Dr. Goodell examine her. An examination made at this time revealed a complete tear of the perineum through the sphincter ani muscle, and a stricture of the rectum of moderate width near the anus. Its lumen was very much contracted, barely admitting the end of a finger. From the dense, fibrous feel of the stricture, it evidently involved all three coats of the intestine.

The treatment in this case was general, as well as local. The pain from the stricture was allayed, in a measure, by cocaine which was used most efficaciously in the form of a suppository, and the bowels were kept in a soluble condition by regulating the diet, and by the administration from time to time of enemata or of mild laxatives. Medicines of a tonic character were freely exhibited.

After one week's stay in the hospital the woman was etherized, and the stricture was forcibly dilated by means of fingers, by Dr. Goodell. An opium suppository was inserted, to allay pain after the stretching had been completed.

The treatment now resorted to in order to restore the part to its normal calibre was the introduction of well oiled bougies every second or third day and finally every day. Previous to their use, a suppository of cocaine was inserted in the rectum, and this did much to prevent pain, though it did not entirely stop it. The cocaine was also used before and after each movement of the bowels. Iodoform suppositories, containing 2½ grains each, were ordered to be inserted both night and morning, in order to disinfect the parts as much as possible.

Not quite a month after the forcible dilation of the stricture, under ether, the patient was discharged and advised to continue the above treatment and come back to the hospital in the course of a month or so. At that time she was able to have a stool with comparative comfort; the feces passed being nearly of normal calibre.

Dr. Goodell does not intend to operate upon the tear of the perineum until the stricture is fully dilated. At the present writing the woman has not presented herself at the hospital, but when last heard from through her family physician, she was doing well.

It is true that hardened feces may occasion stricture; but the history of this woman, whose bowels of necessity had been kept costive ever since her first child was born—that is for over eight years before the stricture appeared—seems to show that this is not necessarily the case. It is equally true, that a stricture may exist for months and years, without causing a patient any uneasiness,[1] but this is the exception to the rule; and I, therefore, take it that, in the case just described, the evidence points to a specific origin of the stricture.

41 N. Twelfth St.

VALVULAR INCOMPETENCY DUE TO BLOOD STATE AND SIMULATING UNCOMPENSATED ORGANIC DISEASE; DISAPPEARING UNDER IRON AND ARSENIC.

BY FRED. JENNER HODGES, B.Sc., M.D.,
HOUSE PHYSICIAN, COOK COUNTY HOSPITAL, CHICAGO.

History.—On May 5, 1889, William Zellar, a German laborer, single, aged 45, was admitted to the Cook County Hospital, suffering from chronic diarrhœa and marked anæmia. His mother died of cancer of the uterus; his further family history was negative. The patient states that he usually drinks a pint of beer daily, but denies having had any venereal disease, although he has had sore throat at various times. At the age of 12, his spine gradually became curved, forming a marked scoliosis, with the convexity to the left. The curvature begins at about the third and terminates with the eleventh or twelfth dorsal vertebra, and at the point of its greatest deviation is about four inches from the median line. The sternum is also deflected to the left. The curvature never caused pain, and soon became—as it has since remained—stationary.

Present Illness.—Some time before last Christmas the patient began to have a rather profuse diarrhœa; often having from three

[1] Thos. G. Morton, M.D., and Henry M. Wetherill, M.D., Pepper's System of Medicine, Vol. II., p. 886.

to six or more, thin yellowish or brownish passages a day, and this condition continued up to the time of his admission. At about the same time he began to be troubled with dyspnœa on the slightest exertion, and had a heavy sensation in the epigastrium, aggravated by taking food. For two weeks he has been unable to retain solid food, and has noticed that his feet have been swollen at night.

Examination.—Temp. 97.8°; pulse 96°, abrupt but compressible; respiration 20 per minute, with some orthopnœa. Patient complains of little or no pain; has no cough; passes urine easily and in fair quantity; but cannot sleep on account—as he says—of nervousness. To the eye the patient presents the familiar picture suggested by the word,—"cachectic." He has little or no adipose tissue, and but slight muscular development; he has pallid or blueish mucous membranes, and a tawny, yellowish skin, but no discoloration of the conjunctivæ. His respiratory sounds are weak; otherwise the examination of his lungs is negative. The splenic area is enlarged. Firm pressure over liver causes some pain.

At the apex of the heart a systolic blowing murmur can readily be recognized, and less easily a presystolic murmur. At the base, along the left side of the sternum, the systolic murmur may be recognized as well as a marked accentuation of the second sound, with some roughening. Over the arteries of the neck a short distinctly double second sound is heard, while the veins give a pronounced hum. Compression of the veins causes, on the proximal side of the compressing finger, a marked accumulation of blood, pulsating strongly.

Microscopic examination of the blood shows a marked relative increase[1] of white corpuscles. The red corpuscles are very irregular in shape and size, the round form being the exception, while the majority are oval, and not a few have irregular prolongations. As to size, the majority are—as compared with specimens from a half dozen other sources—nearly a fourth larger than normal.

Treatment.—Two or three drachm doses of bismuth subnitrate, given in milk, sufficed to check completely the diarrhœa of five months' standing, and the patient was, at the same time, put upon moderate doses of digitalis for two days, to make possible a more satisfactory examination of the heart. This examination however only served to confirm the results of the former one. Anæmia being so marked a feature of the case, the digitalis was replaced by a mixture containing ten drops of Fowler's solution, and two and one-half grains of Valet's mass, given after meals. The patient had before complained of dizziness upon attempting to stand, and, as such attacks began to recur, he received drachm doses of the fluid extract of ergot every four hours for a few days, with considerable benefit. The iron and arsenic were continued, however, with such intermissions as were necessary, for four weeks, with an obvious and continued improvement as regards the œdema, color and digestive symptoms. Having occasion at this time to examine the heart, I was not less gratified than surprised to find the sounds entirely normal, and that, where formally compression of the superficial cervical veins caused a proximal accumulation, showing pulsation, the accumulation now occurred on the distal side of the compressing finger, and of course exhibited no pulsation.

The patient has remained under observation up to the present time (June 12, 1889), but without the slightest abnormality of the heart sounds or any of the symptoms of an uncompensated heart lesion, which were so prominent upon his admission.

[1] Actual proportion could not be determined from lack of proper instruments.

AN IMAGINARY TÆNIA.

BY SOLOMON SOLIS-COHEN, M.D.,
PHILADELPHIA.

Dr. J. Solis Cohen, in his work on Diseases of the Throat and Nasal Passages, published in 1879, records a case of hysteria, in which the epiglottis had been mistaken for a water-snake living in the œsophagus and paying an occasional visit to the mouth, physicians having sat by the patient for hours at a time, to watch it and try to catch it with forceps.

On May 25, 1889, Miss K. W., an hysterical patient, under my care for gouty kidney, called and informed me, with great seriousness, that the diet of milk and under done meat upon which she had been placed had given her a tape-worm; and that it came up in her throat and choked her; and she could feel it when she put her finger back. It felt broad and hard. On one occasion the finger came out bloody; and she was convinced that the worm had bitten her!

Laryngoscopic examination showed that the epiglottis was rather long, and that it had been subjected to a great deal of irrita-

tion, probably from the finger. Cocaine was applied, and the patient was assured that what she had felt belonged in her throat. In addition, appropriate treatment for globus hystericus was instituted.

SOME NEW INSTRUMENTS.

BY WM. S. FORBES, M.D.,
PROFESSOR OF ANATOMY AND OF CLINICAL SURGERY, IN THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

These instruments I placed before the Philadelphia County Medical Society at one of its meetings of late.

The forceps is represented about two-thirds actual size in Fig. A, 1. When applied to the severed extremity of a blood vessel, large or small, it arrests the flow of blood at once. The operator, leaving the forceps *in situ*, can proceed with his operation, undisturbed by hemorrhage, until he has completed his work, when he can apply a ligature more easily, safely and rapidly over the arched beak of the forceps than he can over the tenaculum or any other instrument I have ever used.

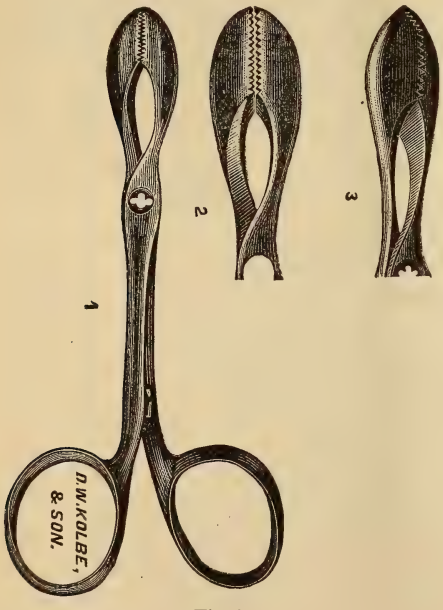

Fig A.

The surface on the curved beak of the forceps—represented at Fig. A, 2 & 3 of actual size, and in two different positions—over which the ligature glides to its destination on the vessel, has just the same curvature the tenaculum has where it penetrates the vessel and neighboring tissue, with its point sticking up to wound the operator's fingers, while he is sending the knot home, and while the blood is still escaping.

The commonly used duck-bill forceps does not permit the ligature to glide over its extremity.

What time is lost in endeavoring to escape the extremity of the duck-bill forceps and place the ligature on the artery? How often does the assistant find his ligature on the extremity of the duck-bill forceps, and not on the artery?

I have used these forceps now, for some time, in abdominal work as well as in general surgical work, and I know of no other instrument that accomplishes so well the important object in view, of completely arresting hemorrhage and, at the same time, of allowing a ligature to be safely and rapidly applied.

Their smaller size, their lighter weight, and the exactness with which they can be applied to a bleeding point and allow a ligature to be easily placed, make them useful.

The saw which is represented at Fig. B, I devised for opening the vertebral canal

Fig. B.

throughout its entire extent, from the occiput down, in order to examine, *post mortem*, the spinal cord and its meninges.

I have found it to work easily and perfectly well.

1704 Walnut Street, Philadelphia.

Society Reports.

PHILADELPHIA NEUROLOGICAL SOCIETY.

Stated Meeting, April 22, 1889.

Held at the Hall of the College of Physicians. Dr. Wharton Sinkler, Vice-President, in the Chair.

Apparatus for Suspension for Spinal Disease.

Dr. J. Madison Taylor exhibited the apparatus devised by Dr. S. Weir Mitchell and used at the Infirmary for Nervous Disease in the treatment by suspension. In all the older forms of sling used in the treatment by suspension, the weight of the body rests chiefly on a support placed under the arm-pit. It is only possible to allow a very moderate amount of pull upon the head. The increasing pressure upon the axillary tissues so affects the bloodvessels of the arms as practically to cut off the pulse at the wrist, and the larger nerve trunks are very seriously affected. In the case of very heavy people, it is found that this becomes so grave a matter that the needed extension of the trunk is limited by the amount of their endurance of the pressure pain. Observing this, it occurred to Dr. Mitchell to apply the support under the elbows—a vastly more comfortable plan.

With this modification it has been found possible to extend the *séance* indefinitely—in certain instances to ten or even twenty minutes.

The adjustment of the head-support is made after the patient has been hoisted by the elbows. This is effected by one of the two plans described in the *Medical News*, April 13, 1889. We use more frequently the device which you see here. To the cheek piece, on each side of the head, a cord is attached which passes over hooks about fourteen inches apart and depends from the transverse bar, and thence passes downward and backward to the rear of each elbow-leather, and there is adjusted by a strap and buckle.

This mechanism may be very readily used in applying plaster jackets, by omitting to use the lower of the two encircling straps.

Dr. J. P. C. Griffith: There is a modification in this apparatus which I do not like. In the original form as adopted by Charcot, and described and illustrated in a recent number of *Le Progrès Médical*, the bar from which the straps are suspended is straight; not curved, as in the one here exhibited. This rod is provided with notches, and the tension of the head piece can be nicely graduated, by sliding the rings from one notch to another. The straps and buckles are serviceable for adjusting approximately the suspension of the head. A most delicate and accurate adjustment can then be procured by using the notches. Time is also saved in this way, where a number of cases have each day to be suspended from the same apparatus.

Dr. Taylor, in reply to Dr. Griffith, said: I do not think that Dr. Griffith would like that method of elevating the head piece by means of sliding the rings over notches so well as this I have described, if he had any practical experience in using both. We have, and find this infinitely more comfortable. Also, if he had seen the second cross-bar and pulley attachment used, he would find it very nice to adjust and agreeable to the subject.

Exhibition of a Tumor of the Brain.

Dr. James Hendrie Lloyd, said: I have here an interesting specimen of brain-tumor, for the opportunity of exhibiting which I am indebted to Dr. S. S. Stryker, of West Philadelphia. I never saw the patient in life. The autopsy was made by Dr. William E. Hughes. The history which I have gathered is as follows. The woman was 63 years of age, and twenty-five years ago had her first epileptic fit. This came on at the close of a period of great mental strain and physical effort in nursing her sick children, one of whom died. It was decided that she and a remaining child should go into the country for rest. At the end of a ride of twenty miles, on a hot summer day, she had her first fit. She was then about forty years of age. Since then she had more or less frequently repeated epileptic seizures. Dr. Stryker has had the case under observation since 1871. The case was regarded as one of epilepsy with more or less mental deterioration. Within the last year it was noted that there was some increase in the size of the head. The right side especially was bulging. The right eye was a little more prominent than the left. One week ago, she was taken with right sided hemiplegia which was spastic in character. The arm was kept tightly across the chest, and it was with difficulty that it could be straightened out.

At the autopsy, which was made to-day, we found that there was great thickening of the skull. I have here a section of the bone, which is fifteen-sixteenths of an inch in thickness. In some parts, the skull cut like cheese, and the bone was of a blueish color. A large tumor was found on the left side, between the temporo-sphenoidal and the under part of the frontal lobe. It is apparently sarcomatous in character. It has a gritty feeling, as though it contained sandy deposits. The neighboring convolutions have been hollowed out by the tumor. The upper surface of the left hemisphere was covered with dark coagulated blood, the immediate cause of death being sub-dural hemorrhage.

An interesting point about this case is that for twenty-five years this woman has been a confirmed epileptic, and has had gradually developing secondary changes in the skull. There is in this brain no evidences of pachymeningitis hemorrhagica. There is simply this history of epilepsy, with gradual failure of mental power, and gradual increase in the thickness of the skull. This case has not been studied with the view of localizing the growth. Dr. Stryker's diagnosis was a tumor of the brain, but he did not attempt to determine its situation. It is not possible, of course, to tell the structure of this tumor before a microscopic study of it is made. The long duration of the case is, to me, one of its remarkable features. Epilepsy coming on in middle life, as in this case, is usually due to some structural changes, as trauma, neoplasm, or degenerative processes. Can it be possible that this tumor, slowly growing, has been the cause of epileptic seizures for twenty-five years? In a table of one hundred cases of brain tumor appended to the paper on brain-tumor by Dr. Mills and myself, in the Am. Syst. of Medicine, the longest duration authentically reported was three years.

—Carpenter recently exhibited to the Hunterian Society of London a child three years old, born without an iris, and having very pronounced nystagmus. The eye was otherwise normal. The child presented another deformities consisting of a congenital pes equino-varus, which was operated on soon after birth. The mother had left internal strabismus, nystagmus, and complete absence of the iris. The mother and sister of the child are healthy, and the deformity is not present in either maternal or paternal grandparents.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, June 6, 1889.

The President, ALFRED L. LOOMIS, M.D., in the Chair.

DR. P. A. MORROW read a paper on

Personal Observations of Leprosy in Mexico and the Sandwich Islands.

He began his remarks by saying that leprosy, to the majority of persons, possesses an historical interest only. They place it in the category of pestilences and plagues, which formerly devastated countries but which are now extinct. Unfortunately, however, leprosy can not fairly be thus regarded, for it is a living reality. In extent it embraces fully one third of the earth, and all varieties of climate and soil; it is present in India, China, Japan, Egypt and elsewhere in Africa, in South America, and in the islands of the Pacific, etc. Whenever it makes its appearance in a new country it can be traced to a human agent; it never originates spontaneously. It was, for instance, introduced into the Northwestern States by the Scandinavians, into California by the Chinese, into other places by the French. Dr. Morrow has learned, during his voyage of study, that there are also cases in Salt Lake City, which were brought by Mormon converts from the Sandwich Islands. Dr. Morrow saw a number of cases in Mexico, and half a dozen in the pest house at San Francisco; but the best place for studying the disease is in the Sandwich Islands. There it has been of comparatively recent introduction. There are many cases in the leper settlements, which afford a good opportunity for investigating the questions of heredity, contagion, etc.

The greatest advances in the study of the disease have been made in the past twenty-five years by modern methods. Our positive knowledge of it may be formulated as follows: It is a parasitic disease; the leper bacillus presents certain analogies with that of tuberculosis. Like the latter, it is endowed with remarkable vitality; like all specific microbes, it shows an affinity for certain fluids and solids of the human organism. It is found both in diffused and also in nodular infiltrations upon the skin and mucous membrane; it is abundant in the lymphatic glands and spaces; it is present in the liver, spleen, and testicles, and is abundant in the connective tissue and

peripheral nerves. It is absent from the blood, the urine, and physiological secretions. It is present in vaccine pustules. The author said it originates only from persons affected with leprosy, and does not attach itself to the soil, water, air, or food. Leprosy has a more or less prolonged stage of incubation, varying from three to four years; and in some instances the stage is supposed to be prolonged twelve or fifteen years. It is slow and irregular in course, and progresses almost invariably to a fatal termination.

Belief in the contagiousness of leprosy was almost universal until, in 1867, the Royal College of Physicians of London expressed the view that it is not contagious; their dogma was very commonly accepted in Europe until recent years. In America, however, leading dermatologists do not accept the heresy of non-contagion. The history of its development in the Sandwich Islands affords the most striking evidence of contagion. Dr. Morrow has had an opportunity to examine a great many cases there, and his experience is like that of most others, namely, that in almost every instance one can get a history of exposure, either in sexual relations or by prolonged intimate contact. A fact of note is, that many of the helpers, usually relatives or friends of the afflicted, sent to the settlements and well when they went there, become lepers themselves after a time. Then there are foreigners who become lepers after a stay in the Sandwich Islands, although the disease is unknown in the country whence they come. The majority of cases probably develop from sexual contact; but in some instances it is due to contact with an abrasion of the skin or mucous membrane. One patient told Dr. Morrow that he had acquired leprosy from the bite of a leper; another said he had acquired it from sticking into his skin a pin which a leper had used in the same way. It seems to have been spread at points in the islands by vaccination with virus obtained probably from lepers. Dr. Morrow has had an opportunity to examine the criminal who had been condemned to death, and given a choice between the death penalty, and inoculation with leprosy virus and imprisonment for life. He chose the latter, was vaccinated in 1884, and for some time his case was thought to be negative; but now there are, to Dr. Morrow's mind, undoubted signs of leprosy; and he found the bacillus of leprosy in the tissues at the former seat of inoculation.

The speaker does not believe leprosy is directly hereditary in the sense that the bacillus is transmitted from parent to offspring; but he thinks a predisposition to the disease may be transmitted, just as in tuberculosis. There is no record of a case of congenital leprosy. The disease never manifests itself before the third or fourth year; the majority of cases develop between the thirtieth and fiftieth years. The disease shows a certain analogy to late hereditary syphilis. He believes that in nearly all cases of so-called hereditary leprosy a careful investigation will reveal contagion through intimate relations with the diseased after the child's birth.

Dr. Morrow threw on the screen photographs of individuals and groups of individuals affected with leprosy, whom he had seen in California and the Sandwich Islands. In one instance the tubercular infiltration involved the skin of the penis, a place in which it has been supposed never to manifest itself. Some of the patients had the tubercular, others the anæsthetic, and others mixed forms of the disease. Dr. Morrow thinks the anæsthetic form is slightly if at all contagious; and this fact accounts in part for the slight spread of leprosy in some communities in which it has gained an entrance. In some places the tubercular form predominates, in others the anæsthetic; but there are always a sufficient number of the tubercular or mixed varieties to keep up the contagion.

The Danger of the Spread of Leprosy in the United States.

This was the subject for general discussion, which was participated in by Drs. C. W. Allen, L. D. Bulkley, G. H. Fox, H. C. Piffard, R. W. Taylor, and P. A. Morrow. Drs. Allen, Piffard, and Morrow thought legislative action should be taken to prevent the entrance of lepers into the United States, and to cause segregation of those already here. Dr. Piffard thought quarantine laws should prevent their further admission, and that the general government might establish a hospital where such as chose could enter without cost; while enforced segregation, if necessary, could be carried out by the States. All the speakers admitted the contagiousness of the disease, but some thought the immediate danger not very great, and Dr. Fox expressed himself as decidedly opposed to creating any alarm. Leprosy, he said, does not spread in civilized countries; there are few cases here, the contagious element is very weak. We assume many other dangers of much greater

gravity without any necessity for doing so; we are ten times as likely to get syphilis, and about as likely to get hydrophobia on account of the presence of dogs in our midst; yet that danger does not lead people to kill off all the dogs.

Dr. Morrow said in reply to Dr. Fox that the Sandwich Islanders could no longer be regarded as barbarians; they are cleanly, and much less filthy and crowded than people in the New York tenements; yet leprosy prevails to an alarming degree there.

Foreign Correspondence.

LETTER FROM BERLIN.

(FROM OUR SPECIAL CORRESPONDENT.)

On Hydracetin, the new Antipyretic and Analgesic.—Bronze Coloration in Miliary Tuberculosis.—The Latest Regarding Tuberculosis.—Singular Tolerance of Iodide of Potassium.

Berlin, May 17, 1889.

In the last meeting of the Berliner Medicinische Gesellschaft, Dr. Guttmann read a highly interesting paper on *hydracetin*, the new antipyretic and analgesic. The drug is, chemically speaking, an acetylphenylhydracin, but as the mere enunciation of this appalling word might produce disastrous consequences in typhoid fever or neurotic disorders, hydracetin will do well enough. A still more felicitous designation for the new drug is the one adopted by English chemists, viz.: pyrodin. The drug, as presented by Dr. Guttmann to the Society, was a white crystalline powder, without taste and odor, soluble in water in the proportion of one to fifty, but easily soluble in acetic acid. Experiments made on various animals show the toxicity of the drug even in small doses. Rabbits receiving 7 or 8 grains by the mouth, or injected into the peritoneum, perish in a day; in a single case even 4 grains proved fatal. A *post-mortem* examination made by Guttmann on five animals, revealed the following: Liver, spleen, and lungs were of a brown-red color; blood was present in the heart and in the vena cava, and the coloring matter of the blood, but no blood corpuscles, in the bladder. Microscopic sections of the kidneys and the liver showed a brown detritus in the vessels and urinary tubules, evidently the result of decomposition of red-blood corpuscles. The same toxic action results from the direct application of the drug to the heart. The new chemical is a reducing agent, and its action is the result of its power to absorb oxygen.

Hydracetin shows even in small doses a powerful antipyretic action, as has been found by Guttmann in 8 cases of typhoid fever, 3 of consumption, 2 of scarlet fever, 1 each of erysipelas, acute miliary tuberculosis, and septicæmia. The average dose of the drug is two to three grains, though five grain doses have also been exhibited by Guttmann. All measurements of temperature on patients under the influence of hydracetin were made in the hours from 10 A.M. to 12 M., when no spontaneous fall of the fever was looked for. If two grains of the drug are given at about 10 o'clock in the morning and one and a half grains an hour later, the temperature begins to fall half an hour after the administration of the drug, and reaches its lowest level in two or three hours. The fall amounts to two or three degrees Centigrade—in some cases even to three or four degrees. The period of apyrexia lasts, however, but a short time, the temperature rising again with moderate slowness and regaining its former height in three to five hours. Perspiration sets in during the fall of temperature, as is the case with all other antipyretics, but disappears as soon as the lowest level has been reached. The frequency of pulse and respiration is lowered simultaneously with the fall of temperature. Regarding the affections themselves, the drug of course showed no influence whatever.

The action of hydracetin in acute articular rheumatism, as tested by Guttmann in eight typical cases, deserves the practitioner's special attention. A two-grain dose affords a distinct remission of pain, beginning one-half to one hour after the administration of the remedy, and lasting for several hours. A two-grain dose, given both in the forenoon and in the afternoon, suffices to remove the pain completely or, at least, to alleviate its severity. The analgesic action of hydracetin was found to be a constant one and did not fail in a single instance. This feature of promptness and reliability of course materially enhances the therapeutic value of the drug. Both its antipyretic and its analgesic action are to be ascribed to its reducing power. Guttmann then showed some interesting color reactions of the drug. Hydracetin, added to an alkaline solution of copper, precipitates the red suboxide of copper and when added to an alkaline solution of silver, precipitates metallic silver. If the crystals of hydracetin are dissolved in

$H_2SO_4 + HNO_3$ (sulphuric plus nitric acid) in the proportion of eight parts of the former to two of the latter, a beautiful red coloration appears immediately. In the urine of a person who had taken the drug for some time, only small quantities of reducing agents could be detected.

Guttmann obtained also gratifying results with the new remedy in two cases of psoriasis, employing a lanolin salve containing 10 per cent. of hydracetin. The first case was only of five days' standing, and was cured in seven days, inunctions having been used daily. Equally beneficial results were obtained in two cases of sciatica, where the analgesic action of the drug was found to be wonderfully prompt. Guttmann, in concluding his remarks, advocated further trials with this promising remedy; but he advised some caution in its internal exhibition, as he had noted in three cases pallor of the face after four-grain doses. This symptom—which, however, soon disappeared—Guttmann ascribes to the dissolution of the blood, produced by the drug, as proven by his experiments. In two-grain doses hydracetin is, in the author's opinion, a safe and welcome remedy for fevers, acute articular rheumatism, and neuralgia.

At the same meeting of the Society, Dr. Lehfeld showed interesting specimens of bronze coloration of the skin, occurring in connection with general miliary tuberculosis. The clinical history of the subject from whom the specimens were taken gives the following points: A young man, 18 years old, four weeks before his death, had loss of appetite, diarrhœa, fever, great emaciation, and an intense bronze coloration, especially noticeable on the extremities. The temperature and pulse were normal. The diagnosis was: Bronze coloration and intestinal tuberculosis. On the next day, the patient had intestinal cramps, became collapsed, and died on the following day. The autopsy showed that the heart was normal; in the superior anterior part of the right lung was an old cheesy focus, besides tubercular tracheitis. The abdominal organs showed miliary tuberculosis, the liver and kidneys being crowded with tubercles. The interior of the intestines showed follicular swelling, and the suprarenal capsule a complete cheesy degeneration.

The recent investigations of Dr. Cornet and Koch, of the Berlin Hygienic Institute, on the mode of propagation of the bacillus tuberculosis, followed by stringent police regulations concerning the treatment of consumptives and their sputa, have revived the interest in the therapeutics of consumption. This interest, though at no time extinct, has always had its periods of greater or less activity, in accordance with various accidental events. It will be opportune, therefore, to review at present the latest researches on this subject, as recorded in European journals. In the *Centralblatt für Bakteriologie*, No. 8, 1889, we find the experiments of Grancher and Gennes on the disinfection of the tubercle bacilli. These observers confirm the assertion of Petri, that the expired air of consumptives is not contagious. A one per cent. solution of corrosive sublimate produces a thorough disinfection of the sputa in twenty-four hours. The best and cheapest apparatus for the disinfection of spittoons, is that of Geneste and Herscher, which disinfects twenty-four spittoons in an hour by means of steam.

Of considerable interest is a recently published pamphlet of Dr. Petrescu, of Budapest, on the prevention of the contagiousness of consumptives. The author uses a Drechsel bottle (such as is used in chemical laboratories for the washing of gases), which he has transformed into an inhalator for volatile substances. The principle of this apparatus is the same as that of the Turkish Nargileh, or water smoking-pipe. Air having passed through sterilized cotton and the antiseptic contents of the bottle, is sucked up by means of an India-rubber tube. As contents of the bottle, Petrescu orders usually:

℞ Iodoform . . . . . gr. xv
Eucalyptol,
Creasote,
Turpentine . . . . . āā ♏xxx
Distilled water . . . . . f℥iii

Sig. For two days' inhalation.

The idea of the author is to produce, by the prolonged antiseptic inhalations—extended over months and years—a saturation of the organism with microbicide substances, and thus to render the former an unfavorable soil for the development of the bacillus tuberculosis. In this manner he thought of exercising not only a prophylactic but also a curative influence over the tubercular process. But, unfortunately, such an assumption is an erroneous one, as real disinfection of the organism can never be attained by minimal doses of volatile agents, this bacillus having an extremely tenacious life. His apparatus, nevertheless, answers very well as an inhalator. Far more convenient, however, for obtaining the same result are the so-called "nasal capsules" of Feldbausch. The

present desideratum in the therapeutics of tuberculosis is evidently not the prevention of the contagiousness of the sputum previous to expectoration, but after it. To effect this, however, stringent police regulations are a *conditio sine qua non.*

Of equal interest are the experiments of Prof. de Renzi, on the treatment of tuberculosis with hot air. He has formulated his results, obtained in eight cases of tuberculosis, as follows: 1. To produce beneficial effects the air must be of a temperature of 140° C. (284° F.). 2. The inhalations must be continued for one-quarter to one-half an hour. 3. The inhalations improve the general feeling, appetite, and innervation of the patients. 4. They also increase their bodily weight. 5. They are invariably well borne.

Prof. Mangardi has again taken up hydrofluoric acid as a remedy in tuberculosis, and publishes in some Italian journal very favorable results from its use.

The following note of a German military surgeon illustrates the great tolerance by some persons of iodide of potassium: A soldier emptied in 12 hours a bottle containing a solution of three hundred grains of iodide of potassium in eight fluid ounces of water, without experiencing any deleterious effects.

PERISCOPE.

Origin of the Yellow Fever on the "Boston" and "Yantic."

Dr. William M. Smith, the Health Officer of New York City, in his annual report to the Board of Commissioners of Quarantine, gives in some detail the history of the occurrence of yellow fever on the U. S. cruiser "Boston" and on the U. S. sloop-of-war "Yantic." Dr. Smith says that neither the "Boston" nor the "Yantic" received anything on board from the shore while at Port-au-Prince, except meal and fruit. The fruit, consisting of bananas and oranges, was taken to the vessels by natives, in what is called "bumboats," and sold to those on board. The main decks of the "Boston" and "Yantic" are so low, that communication between those on them and the "bumboats" was easy, and doubtless frequent, while the natives were vending their fruit. The wet, dirty, and sun-heated bottoms and timbers of the boats of the natives, exposed, as they must be at all times when at the shores or wharves, to an infected atmosphere as well as to the infected filth of the gutters that drain into the bay, certainly supply all the conditions necessary for the propagation of the infection. It would be rather a matter of surprise than otherwise, if the boats of the natives were not impregnated with the infection of yellow fever when it prevails at Port-au-Prince. The history of the disease on the "Boston" and the "Yantic" affords satisfactory evidence to Dr. Smith that the persons who suffered from it contracted the infection while at Port-au-Prince, and that the infection did not infect either vessel; in other words, that the infection was limited to the individuals who contracted the infection at that port.—*Science*, April 19, 1889.

Large Gumma in the Nostril.

Dr. S. G. Dabney reports the following case in the *American Practitioner and News*, Feb. 16, 1889:

Mr. B. was referred to me by Dr. A. M. Cartledge on the 10th of last November. He gave this history: was twenty-eight years old, married, and the father of several healthy children; he denied having had syphilis. Four or five weeks previous to his visit to me he noticed an obstruction in his right nostril; this had rapidly increased, until respiration through that side was prevented; there was sharp pain in the nose and over the whole of that side of the head. On examination I found a growth over the lower left turbinated bone, occluding that nostril and pressing against the septum. The growth was hard and sensitive to pressure; the surface toward the septum was ulcerated; the corresponding ala of the nose bulged outward. The lymphatic glands at the angle of the lower jaw and in the neck of the same side were enlarged, but no involvement was to be detected elsewhere. From the rapid growth, sharp pain, and implication of the neighboring glands, a malignant tumor seemed probable, all the more so, as the patient denied any taint of syphilis. Notwithstanding this, however, I prescribed fifteen grains of iodide of potassium three times a day, and soon increased the dose to thirty grains. No symptoms of iodism were produced, and the growth very rapidly disappeared; it seemed almost to melt away, thus establishing its syphilitic nature. The man afterward confessed that he had had a sore on his penis ten years before, and had taken some medicine which a doctor prescribed for him, but gave no further history of constitutional syphilis.

P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

The meeting of the American Medical Association, held in Newport this week, was attended by about seven hundred delegates and members. Owing to the fact that the place of meeting was so far in the East, the attendance included many physicians living east of the Allegheny Mountains, but there was a large number of western and southern men present.

One of the most interesting questions which came up for decision referred to the choice of an Editor for the *Journal* of the Association. This came directly before the Trustees; but the members of the Association—who are so deeply interested in the matter—did not leave the Trustees without such suggestions as might indicate their views as to the principles upon which a choice should be made. No Editor, however, was selected, and no change was announced in the editorial management. For Trustees of the *Journal*, the present incumbents were continued, with the exception of Dr. Hamilton and Dr. Moore, in whose stead Dr. W. W. Dawson, of Cincinnati, and Dr. I. N. Love, of St. Louis, were chosen.

Another interesting question related to the place for the next meeting. There was a general understanding that Philadelphia might be considered, if this would be agreeable to the profession in that city; but on mature consideration it was decided to meet in 1890 at Nashville, Tennessee.

Important amendments to the fundamental laws of the Association came before the meeting. The most important was that substituting for the Nominating Committee a "General Committee," composed of two members from each State and the Army, Navy and Marine Hospital Service, one to be elected to serve for two years each alternate year. None of the amendments was adopted.

A few modifications—elsewhere recorded—were made in regard to the name and scope of the sections.

The entertainments provided for the pleasure of the members of the Association were excellently arranged, and the social features of the meeting were very agreeable.

The meeting was successful in a scientific sense, the papers being numerous and valuable, and the discussions thorough and instructive. It will be remembered as one at which much good work was done, and much was accomplished to strengthen the bond of kindly feeling between the members of the medical profession in all parts of the broad territory of the United States.

RAILWAY SPINE.

One of the most curious developments of modern medical study, and one with an extremely important practical bearing, relates to a form of disorder following railway accidents, which is known by the name of "railway spine."

To those unfamiliar with the manifestations of this disorder, it would appear almost incredible that it should play so serious a *rôle* in the lives of persons who have received injuries which often seem far from severe, and be so often the occasion of protracted medico-legal contests. But one who has studied its phases, under circumstances favorable to a just discrimination between actual morbid phenomena and the simulations which are sometimes practised in order to wring money from a rich corporation, will not wonder that it is regarded as a very grave matter by medical experts, and that they warmly resent the common impression that it is frequently only a form of malingering.

There can be no doubt that instances occur, in which an avaricious patient and a willing or pliable physician unite to overestimate the damage done by a railway accident; but these cases are far more rare than is often supposed, and there is, on the whole, more danger of error in being too skeptical of the real existence of a condition for which no better name has yet been suggested than "railway spine," than there is in recognizing it and endeavoring to estimate it justly.

The cases which give most trouble are those in which there are few or no evidences of gross lesions in the spinal cord or its surrounding hard and soft parts, but in which there are manifestations of nervous disorder, following an accident and attributed to it, which may be deliberately affected from motives of cupidity. To discriminate between sufferers and pretenders, under these circumstances, is by no means an easy or a pleasant task for most medical men. But much help may be gained for the task by a study of what has been written by men of experience in such cases. A valuable paper on the subject, by Dr. Dercum, of Philadelphia, is in the Department of the REPORTER for Pamphlet Notices, No. 296. In this pamphlet Dr. Dercum describes the classes of injury which are likely to follow blows or falls upon the region of the spinal column, and gives a very instructive review of the principles which should guide a medical witness in deciding upon the actual condition of a person who claims damages for such injuries. We cannot repeat, or even summarize, his conclusions; but would call attention to one point in particular in regard "railway spine," and this is, that there are not a few cases in which, with no gross lesions whatever, a person who has never been nervous, or timid, or hypochondriacal, develops all these characteristics after a railway injury. In women—as Dr. Dercum points out—this alteration of character sometimes takes the form of hysteria, while in the case of men precisely the same condition sometimes follows participation in a railway accident. To give the condition the name of hysteria may be—except for the etymological error of the term—scientifically correct; but to permit this to blind one to the realness of the misfortune would be a grave injustice to the subject of it.

Here is the most delicate question which can arise in the mind of a medical witness; and we believe that it is not untimely to say this word, to fortify any of our readers who may find it hard to meet the objections of counsel for railroad companies, who often honestly think medical men too prone to testify to the existence of evils which are not actually present. The medical witness ought not to ignore the possibility that a claimant for damages may be assuming or exaggerating the appearances of real nervous disorders; but no more ought he to permit himself to be deterred from doing justice to the victim of a railway accident, because there is a natural prejudice against

charging whatever follows such an accident to it.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

289. Diseased Conditions for which Sea Air is of Doubtful Benefit. From the *Trans. of the American Climatological Association.* And, The Restorative Treatment of Sleeplessness from Brain Exhaustion. From the *Journal of the American Medical Association.* By Boardman Reed, M.D., Atlantic City, N. J. 8 pages.

290. Note on Rumbold's Method of Treatment of Catarrhal Inflammations of the Upper Air Passages. By Ely McClellan, M.D., Surgeon U. S. Army. From the *Journal of the Amer. Med. Association,* Jan. 5, 1889. 16 pages.

291. The Medical Jurisprudence of Inebriety. By Joseph Parrish, M.D., Burlington, N. J. From the *Journal of Inebriety,* January, 1888. 7 pages.

292. Das Höhenklima, in meteorologischer, physiologischer und therapeutischer Beziehung. Von Dr. August Ladendorf, St. Andreasberg. From the *Deutsche Medizinal-Zeitung.* Erster Theil. 70 pages.

293. Therapeutics can become a science. By William Sharp, M.D., Rugby, England. 33 pages.

294. On the Relation Between the General Practitioner and the Consultant or Specialist. By L. Duncan Bulkley, M.D., New York. From the *Journal of the Amer. Med. Ass'n,* Feb. 2, 1889. 12 pages.

289. Dr. Reed calls attention to imprudences which sometimes prevent the sea air from doing good to invalids, and also the fact that sea air is not a cure-all, but even seems to act injuriously upon patients affected with certain diseases. In the second half of his pamphlet he impresses the importance of recognizing the fact that sleeplessness is often a manifestation of brain exhaustion and to be treated with tonics and a stimulating hygiene rather than with hypnotics.

290. This pamphlet contains a clear and concise description of the method employed by the author in the treatment of nasal and naso-pharyngeal catarrh, and which has yielded most satisfactory results in his hands. His pamphlet contains illustrations which make the meaning of the text perfectly plain, and it can be recommended to the thoughtful consideration of our readers.

291. The pamphlet advocates the view that the tendency to the intemperate use of alcoholic stimulants is a disease, and cites several interesting cases as evidence of the mental state into which inebriates sometimes fall. Some of these stories sound rather strained, and give the impression that one would need the glasses of the alcoholism specialist to see them in just the same light.

292. A learned study of the conditions of weather, rainfall, sunshine, etc., found at high altitudes in different parts of the world, with a certain amount of allusion to their effect upon the human system in health and disease.

293. This Essay is dated on the author's 84th birthday and indicates that, at this age, he retains a warm interest in theoretical and practical medical questions. The practice recommended covers features which appear not unlike homœopathy and others which are heroic enough for any one. It is interesting reading, though parts of it sound like hobbies rather than scientific theories.

294. Dr. Bulkley's pamphlet contains sound and conservative rules for the guidance of specialists and general practitioners in regard to patients common to both.

Literary Notes.

—Dr. Byrom Bramwell, one of the most enterprising clinical teachers of the Edinburgh School of Medicine, has begun the publication of a new semi-monthly magazine, entitled: "*Studies in Clinical Medicine.*" The object of this new venture in British journalism is to bring to the notice of a large number of persons the results of Dr. Bramwell's examinations of patients who present themselves at his clinic, and to give in an informal manner his remarks—which are taken down in short-hand—upon the treatment of the cases.

Notes and Comments.

New Jersey State Medical Society.

The one hundred and twenty-third annual meeting of the New Jersey State Medical Society was held at Asbury Park, June 18 and 19, 1889. The following officers were elected for the ensuing year: *President,* B. A. Watson, M.D., Jersey City; *First Vice-President,* James S. Green, M.D., Elizabeth; *Second Vice-President,* E. J. Marsh, M.D., Paterson; *Third Vice-President,* George T. Welch, M.D., of Key Port; *Corresponding Secretary,* William Elmer, Jr., M.D., Trenton; *Recording Secretary,* William Pierson, M.D., Orange; *Treasurer,* W. W. L. Phillips, M.D., Trenton. *Standing Committee,* T. J. Smith, M.D., Bridgeton; D. C. English, M.D., New Brunswick; J. G. Ryerson, M.D., Boonton. The meeting adjourned to meet in June, 1890, at Schooley's Mountain.

The Cook County Asylum.

In the Reporter, June 1, reference was made to the disgraceful condition of affairs existing in the Cook County Asylum for the Insane. On June 19, Judge Prendergast, of Chicago, rendered his decision in the matter of the investigation into the management of the Asylum. The decision is a long one, but the central idea is explained in the Judge's reference to the political influences

which were allowed to control the Asylum. The institution, he says, must be removed from the influences of partisanship in order that the "sweet waters of charity may not be polluted by politics." The Judge recommends that the Asylum be removed from its present site, and that a special session of the State Legislature be called to attend to the matter.

College of Physicians and Surgeons, New York.

At the last meeting of the Faculty of this institution, Dr. James W. McLane was elected to the position of President to fill the place of the late Dr. John C. Dalton. Dr. Markoe was re-elected Vice-President and Dr. Curtis, Secretary. One change only has taken place in the teaching Faculty. Dr. Richard John Hall resigns the chair of anatomy because of ill health. The vacancy will not be permanently filled this year. The graduating class this year was the largest yet sent forth by this college; numbering 167.

The Woman's Medical College of Baltimore.

At the annual meeting of the Faculty and Trustees of the Woman's Medical College of Baltimore, held May 1, the clause allowing "one year's study under a preceptor" to stand for one course of lectures was abolished, so that this institution now places itself squarely among the schools having a three-year compulsory course. The sessions are seven months long, and the instruction is graded with written and oral examinations at the end of each year. There has been a preliminary examination (in English only) since 1883. An average of 70 out of 100 is required for graduation.—*Maryland Medical Journal*, June 15, 1889.

Sanitary Condition of Johnstown.

Dr. Benjamin Lee, executive officer of the State Board of Health of Pennsylvania issued a bulletin on June 17, in which the sanitary condition of Johnstown and surrounding boroughs is reported to be excellent, in view of existing circumstances.

Dr. Lee says there has been a gradual improvement in the health of the boroughs. Coopersdale is somewhat inaccessible owing to high water in the Conemaugh, and there are some cases of gastric disorders in consequence of poor food. There have been no cases of contagious disease at the general hospital, and only one fatal case of diphtheria at the Red Cross Hospital and one other case. Among the soldiery there is not a single hospital case. The number of cases of measles is diminishing. Gangs are engaged in collecting the carcasses of dead animals along the different streams and are burning them.

Formula for a Mucilaginous Ointment.

Vigier suggests the following formula in the *Gazette Hebdomadaire*, May 3, 1889:

Vaseline	℥i
Oxide of zinc	℥i
Powdered gum tragacanth	℥ss
Distilled water	f℥iiss
Tincture of benzoin	gtt. xxx
Soap powder	gr. vi

Mix the oxide of zinc and vaseline in a mortar and add a little of the mucilage prepared in another; then add the soap powder and finally the tincture. Mix carefully and preserve in a tight box.

OBITUARY.

J. W. KERR, M.D.

Dr. J. W. Kerr, a venerable and widely-known physician of York, Pennsylvania, died at his residence, June 11, after an illness of two weeks. He was a native of Lancaster County, and was born September 19, 1813. He was graduated from Jefferson College in 1834, and from the University of Pennsylvania in 1839. In the same year he came to York and began the practice of medicine, which he continued without intermission until his death. In 1844 he was married to Miss Jane McIlvain, a native of York. Of three children born, only one survives, Mrs. Dr. W. F. Bacon.

DR. DANIEL W. HAND, M.D.

Dr. Daniel W. Hand died at St. Paul, Minnesota, recently. Dr. Hand was born at Cape May Court House, New Jersey, in 1834. He was graduated at the University of Pennsylvania in 1856, and went to St. Paul in 1857. At the outbreak of the late war, he was commissioned Assistant Surgeon of the First Minnesota Regiment, and was soon promoted to Brigade-Surgeon. He was stationed at Plymouth, N. C., when the yellow fever broke out and remained there through the entire time, nearly one-half the population having died of the fever. Dr. Hand enjoyed the reputation of being one of the ablest physicians of the Northwest. At the time of his death he was Surgeon-General of the State Militia of Minnesota.

List of Members of Senate and House of Representatives of Pennsylvania,

With Post-Office Addresses.

1889-1890.

SENATE.

PHILADELPHIA.

First District. — 1st, 2d, 26th and 30th wards, GEORGE HANDY SMITH, R., 1541 S. Broad st.

Second District.—3d, 4th, 5th, 6th and 11th wards, WILLIAM MCALEER, D., 630 S. Tenth street.

Third District.—16th, 17th, 18th and 20th wards, CHARLES P. DEVLIN, D., 729 Oxford street.

Fourth District.—21st, 22d, 24th and 27th wards, JOHN J. MACFARLANE, R., 430 Walnut street.

Fifth District.—15th, 28th and 29th wards, JOHN E. REYBURN, R., 1715 Green street.

Sixth District.—7th, 8th and 9th wards, BOIES PENROSE, R., 1331 Spruce street.

Seventh District.—10th, 12th, 13th and 14th wards, JOHN C. GRADY, R., 714 Walnut street.

Eighth District.—19th, 23d, 25th and 31st wards, HENRY S. TAYLOR, R., 2203 E. Cumberland street.

Ninth District. — Delaware county, THOMAS V. COOPER, R., Media.

Tenth District.—Bucks county, GEORGE ROSS, D., Doylestown.

Eleventh District. — Berks county, HENRY D. GREEN, D., Reading.

Twelfth District.—Montgomery county, HENRY R. BROWN, R., Norristown.

Thirteenth District.—Lancaster county, AMOS H. MYLIN, R., Lancaster.

Fourteenth District.—Lancaster county, JOHN M. STEHMAN, R., Roherstown.

Fifteenth District. — Dauphin county, ALEX. F. THOMPSON, R., Lykens.

Sixteenth District. — Lehigh county, MILTON C. HENNINGER, D., Allentown.

Seventeenth District.— Lebanon county, J. P. S. GOBIN, R., Lebanon.

Eighteenth District.—Northampton county, JACOB DACHRODT, D., Easton.

Nineteenth District.—Chester county, A. D. HARLAN, R., Coatesville.

Twentieth District. — Lackawanna and Luzerne counties, L. A. WATRES, R., Scranton.

Twenty-first District.—Luzerne county, WILLIAM H. HINES, D., Wilkes-Barre.

Twenty-second District.—Monroe, Pike and Carbon counties, J. H. SHULL, D., Stroudsburg.

Twenty-third District—Bradford and Wyoming counties, J. K. NEWELL, R., Wyalusing, Bradford county.

Twenty-fourth District.—Lycoming, Montour, Sullivan and Columbia counties, V. H. METZGAR, D., Williamsport.

Twenty-fifth District.—Tioga, Potter and McKean counties, H. B. PACKER, R., Wellsboro', Tioga county.

Twenty-sixth District.—Susquehanna and Wayne counties, O. A. LINES, R., Great Bend, Susquehanna county.

Twenty-seventh District.—Union, Snyder and Northumberland counties, S. D. BATES, R., Lewisburg, Union county.

Twenty-eighth District.—York county, GERARD C. BROWN, D., Yorkana.

Twenty-ninth District.—Schuylkill county, LUTHER R. KEEFER, R., Cressona.

Thirtieth District.—Schuylkill county, M. C. WATSON, D., Shenandoah.

Thirty-first District.—Perry, Mifflin and Juniata counties, J. M. WOODS, R., Lewistown, Mifflin county.

Thirty-second District.—Cumberland and Adams counties, WILLIAM A. MARTIN, D., Arendtsville, Adams county.

Thirty-third District.--Franklin and Huntingdon counties, W. MCKNIGHT WILLIAMSON, R., Huntingdon.

Thirty-fourth District.—Clinton, Clearfield and Centre counties, W. W. BETTS, D., Clearfield.

Thirty-fifth District.—Blair and Cambria counties, JOHN A. LEMON, R., Hollidaysburg, Blair county.

Thirty-sixth District.—Somerset, Bedford and Fulton counties, W. SCOTT ALEXANDER, R., McConnellsburg, Fulton county.

Thirty-seventh District.—Indiana and Jefferson counties, HANNIBAL K. SLOAN, D., Indiana.

Thirty-eighth District.—Cameron, Elk, Clarion and Forest counties, J. H. WILSON, D., Reidsburg, Clarion county.

Thirty-ninth District.—Westmoreland county, E. E. ROBBINS, R., Greensburg.

Fortieth District.—Fayette and Greene counties, THOMAS B. SCHNATTERLY, D., Uniontown, Fayette county.

Forty-first District.—Butler and Armstrong counties, J. B. SHOWALTER, R., Barnhart's Mills, Butler county.

Forty-second District.—Allegheny county, JAMES S. RUTAN, R., Allegheny City.

Forty-third District. — Allegheny county, JOHN UPPERMAN, R., Pittsburgh.

Forty-fourth District.—Allegheny county, JOHN C. NEWMYER, R., 98 Diamond street, Pittsburgh.

Forty-fifth District.—Allegheny county, SAMUEL S. STEEL, R., Green Tree, Allegheny county.

Forty-sixth District. — Beaver and Washington counties, J. R. MCLAIN, Claysville, Washington county.

Forty-seventh District. — Lawrence and Mercer counties, THOMAS M. MEHARD, R., Wampum, Lawrence county.

Forty-eighth District.—Warren and Venango counties, O. C. ALLEN, R., Warren.

Forty-ninth District. — Erie county, D. B. MCCREARY, R., Erie.

Fiftieth District.—Crawford county, GEORGE W. DELAMATER, R., Meadville.

HOUSE OF REPRESENTATIVES.

PHILADELPHIA.

First District.—1st ward, SAMUEL STRIEN, R., No. 1345 S. Fourth street; HARRY NICHOLS, D., No. 613 Wilder street.

Second District.—2d ward, JAMES C. HASSETT, D., No. 902 S. Fifth street.

Third District.—3d ward, JAMES D. LEE, D., room 533 Drexel Building, Fifth and Chestnut street.

Fourth District.—4th ward, JOHN DONAHUE, D., No. 727 S. Tenth street. Office, 711 Sansom street.

Fifth District.—5th ward, BRUNO ERNST, R., No. 317 S. Sixth street.

Sixth District.—30th ward, JOSHUA RUSSELL, R., No. 1841 Christian street.

Seventh District.—7th ward, HENRY K. BOYER, R., No. 608-610 Chestnut street.

Eighth District.—8th ward, JOHN M. SCOTT, R., No. 625 Walnut street.

Ninth District.—9th ward, CLENMAR P. HOSKINS, R., No. 1130 Girard street.

Tenth District.—6th and 10th wards, AUGUSTIN S. ROBERTS, R., No. 126 N. Tenth street; FRANK M. RITER, R., No. 231 S. Sixth street.

Eleventh District.—11th ward, GEORGE A. QUIGLEY, D., No. 163 Brown street.

Twelfth District.—12th ward, CHARLES R. GENTNER, D., No. 314 Brown street.

Thirteenth District.—13th ward, JOHN J. MULLANEY, D., No. 815 Depot street.

Fourteenth District.—14th ward, WILLIAM M. KIDD, R., No. 808 N. Twelfth street.

Fifteenth District.—15th ward, JAMES W. WALK, R., No. 737 Corinthian avenue; RICHARD PATTERSON, R., No. 2422 Green street.

Sixteenth District.—16th and 18th wards, WILLIAM F. STEWART, R., No. 311 E. Girard avenue; EDWARD M. CRAIG, R., No. 806 Hewson street.

Seventeenth District.—17th ward, JOHN H. FOW, D., Office, No. 206 S. Seventh st. Residence, 1229 and 1231 N. Sixth st.

Eighteenth District.—19th and 31st wards, HENRY S. MYERS, R., No. 2431 Marshall street; JOHN A. J. ENNIS, R., No. 2407 Emlen street; ERWIN F. KNIGHT, R., No. 2208 Orianna street.

Nineteenth District.—20th ward, WILLIAM H. KEYSER, R., No. 1000 Arch st.; JOHN H. RIEBEL, R., No. 623 W. Girard avenue.

Twentieth District.—21st ward, NATHAN L. JONES, Jr., R., Wissahickon.

Twenty-first District—22d ward, WILLIAM H. BROOKS, R., No. 4756 Morris street, Germantown.

Twenty-second District.—25th ward, JOHN W. BAIN, R., No. 2935 Richmond street.

Twenty-third District.—23d ward, BENJAMIN JONES, R., No. 35 Arrott street, Frankford.

Twenty-fourth District.—24th ward, C. WESLEY THOMAS, R., No. 3903 Lancaster avenue; WILLIAM BUNCH, Jr., R., No. 422 N. Forty-first street.

Twenty-fifth District.—26th ward, JOSEPH G. RICHMOND, R., No. 1304 Federal street; JOHN M. SMITH, R., No. 1714 Dickinson street.

Twenty-sixth District.—27th ward, HORATIO P. CONNELL, R., Forty-sixth and Kingsessing avenue.

Twenty-seventh District.—28th ward, ROBERT R. DEARDON, R., No. 406 Walnut st.; residence, No. 2020 N. Broad st. C. HARRY FLETCHER, R., No. 2813 Fletcher street.

Twenty-eighth District.—29th ward, WILLIAM B. ROSE, R., No. 1912 Nicholas street; SAMUEL C. DINGEE, R., No. 1520 Opal street.

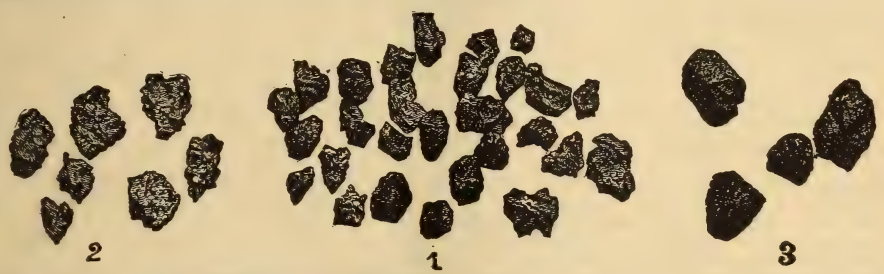
Buffalo Lithia Water

In the TREATMENT OF URINARY DEPOSIT.

Case of Dr. B. J. WEISTLING, of Middleton, Pa., stated by himself.

"Experience in its use in **STONE in the BLADDER** in my own person enables me to attest the efficacy of the **BUFFALO LITHIA WATER** in this painful malady. After having been long subjected to sufferings, the intensity of which cannot be described, I have, under the influence of this Water, passed an ounce of **CALCULI (URIC ACID)**, some of which weighed as much as four grains, affording inexpressible relief and leaving me in a condition of comparative ease and comfort.

"On one occasion I passed thirty-five **CALCULI** in forty-eight hours. The appearance of these **CALCULOUS NUCLEI** indicates unmistakably, I think, that they were all *component particles of one large* **CALCULUS** *destroyed by the action of the Water, by means of solution and disintegration.* At my advanced period of life (I am seventy-seven years and six months of age), and in my feeble general health, a surgical operation was not to be thought of, and the Water seems to have accomplished all that such an operation, if successful, could have done."



[The above plate is from a photograph, and represents the exact size and shape of some of the Calculi passed by Dr. Weistling. They were preserved by his son, Dr. J. Weir Weistling.]

Case stated by Dr. G. HALSTED BOYLAND, late Professor of Surgery, Baltimore Medical College, Member American Medical Association.

"The case of Mr. C., which came under my observation as Resident Physician at the Springs during the season of 1884, affords undoubted evidence that Buffalo Lithia Water is a **SOLVENT** *for Urinary Deposit*, commonly known as **STONE in the BLADDER.** He was operated upon for **STONE**, the operation affording but partial and temporary relief. A year afterward he visited the **BUFFALO LITHIA SPRINGS**, at the same time passing small quantities of a *Urinary Deposit*, of the **TRIPLE PHOSPHATE of AMMONIA** and **MAGNESIA VARIETY**, and his sufferings such as required that he should be kept constantly under the influence of opiates. In some eight weeks the solvent properties of the Water *were evident in the diminished consistency of the deposit, the increased quantity discharged, and by its change from Concrete Lumps to fine Sand*, which he discharged to the amount of *Four Ounces.* After a time, however, the quantity gradually diminished, and finally ceased, and he left the Springs *with the deposit dissolved* and *washed out of the system*, and the *Diathesis fons et origi morbi* altered. There had been a disappearance of the attending distressing symptoms, and great improvement in his general condition."

Dr. MARTIN L. JAMES, of Richmond, Va., Professor of Materia Medica and Therapeutics, Medical Society of Virginia.

[Proceedings of the Richmond, Virginia, Academy of Medicine, December 16, 1880.]

"The President of the Academy, Dr. M. L. James, reported three cases of marked **URIC ACID DIATHESIS** successfully treated by the Water of Spring No. 2 of the **BUFFALO LITHIA SPRINGS** of Virginia. In one of these patients there were, as a result of this Diathesis, **SANDY DEPOSITS** in the *Urine, Inflammation of the Kidneys, Irritability of the Bladder, and Hæmaturia*, and, finally, the passage of a **CALCULUS** of the size of a cherry, formed on a blood-clot as a nucleus. In another case there were frequent attacks of **NEPHRITIC COLIC**, attended by **SANDY DEPOSITIONS** in the urine. After the free use of this Water in these cases, no further manifestations of the disorder occurred."

Dr. HENRY M. WILSON, of Baltimore, ex-President Medical and Chirurgical Faculty of Maryland.

"My experience in the use of the **BUFFALO LITHIA WATER** has not been large, *but it is of such a positive character that I do not hesitate to express my preference for it, as a* **DIURETIC** in **URINARY CALCULI,** *over all other waters that I have ever used.*"

Water in cases of one dozen half-gallon bottles, $5 per case, at the Springs.

THOMAS F. GOODE, Proprietor,

BUFFALO LITHIA SPRINGS, VIRGINIA.

THE NEW HYPNOTIC
SULFONAL-BAYER.

SULFONAL was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

SULFONAL (Diæthylsulfondimethylmethan) is in the form of colorless prisms, odorless, and tasteless, melting at 125.5° C. (258° F.) and has the composition $(C H_3)_2=C=(C_2 H_5 SO_2)_2$. It is slightly soluble in cold water, but easily soluble in hot water or alcohol.

SULFONAL was first examined as to its physiological and pathological effects by Prof. A. Kast, of Freiburg University, and its hypnotic action was discovered and studied by him.

Since then SULFONAL has been the subject of numerous trials and experiments by many eminent and experienced physicians. Their testimony is unanimously favorable, and the conclusions reached by them are as follows:

SULFONAL is a prompt and reliable hypnotic, which in proper doses, produces quiet, natural sleep, lasting a number of hours.

SULFONAL has no unfavorable effects on the heart and the circulation, nor on the temperature, the pulse, or the respiration.

SULFONAL produces no disagreeable secondary symptoms; the patients with very few exceptions awake from their sleep feeling strong and greatly refreshed.

SULFONAL does not interfere with the process of digestion.

SULFONAL is a hypnotic, and not a narcotic; it acts by giving rest to the cells of the cerebral cortex, thereby causing sleep.

SULFONAL does not create an unconquerable desire for its repeated use; there is no danger of a SULFONAL-habit Neither is it necessary to increase the dose after long-continued use.

SULFONAL is best administered at supper-time, dissolved in hot liquids, *e. g.*, a bowl of soup or broth, a cup of milk, tea, coffee, cocoa, etc.

These points will be found to be fully exhibited in the series of contributions contained in our pamphlet which will be mailed on application.

SULFONAL-BAYER is supplied by us in half-ounce and one-ounce vials.

We prepare 5-grain and 15-grain Tablets of Sulfonal-Bayer. The tablet form is admirably adapted to the purpose of administering this drug, as when they are placed in the liquids, they disintegrate and are thus received into the system.

We also put up Sulfonal-Bayer in the form of our Soluble Pills, containing five grains each.

THE NEW ANTIPYRETIC
PHENACETINE-BAYER.

Phenacetine-Bayer (Para-Acetphenetidine) is a white, glossy, crystalline powder, perfectly tasteless, melting at 135° C.=307° F. and has the composition $C_6 H_4 <^{O.C_2H_5}_{NH(CO-CH_3)}$.

It is slightly soluble in water, a little more soluble in glycerine, but most freely in alcohol.

Phenacetine-Bayer was first prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, and is of absolute purity and uniform quality.

Summarizing the superiority of Phenacetine-Bayer over other antipyretics and antineuralgics, the following conclusions are formed:

1. ***Phenacetine-Bayer is an efficacious antipyretic.***
2. ***It does not develop any disagreeable or noxious after-effects.***
3. ***The dose required is half that of Antipyrine.***
4. ***It is perfectly tasteless.***
5. ***On account of its innocuousness and tastelessness, it is a valuable antipyretic both in adults and in children.***
6. ***Phenacetine-Bayer is an important antineuralgic; its effect is more energetic than that of Antipyrine and does not cause lassitude or any other disagreeble symptoms.***

Our pamphlet on Phenacetine-Bayer, containing the valuable testimony of eminent physicians will be mailed on application.

We offer Phenacetine-Bayer in one-ounce vials, or in the form of our Soluble Pills of the strength of two and four grains to each pill.

The Curd of Cow's Milk
Made as Soft and Digestible as that of
Woman's Milk.

"From experiments which I have recently made — and my thanks are due to Prof. Salisbury of the Woman's Medical College, for assistance — it seems that the claim which is made by the advocates of the MELLIN'S FOOD is true, and that the addition of this food to cow's milk does cause it to break up in very small, flaky curds."— *Dr. Chas. Warrington Earle, Professor of Diseases of Children, Woman's Medical College, Professor of Obstetrics, College Physicians and Surgeons, Chicago, in his paper on Infant Feeding, before the American Medical Association, May, 1888.*

Any physician having a case in which he desires to test MELLIN'S FOOD can obtain a sample sufficient for trial, free of all expense, by application.

Doliber-Goodale Co., Boston, Mass.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

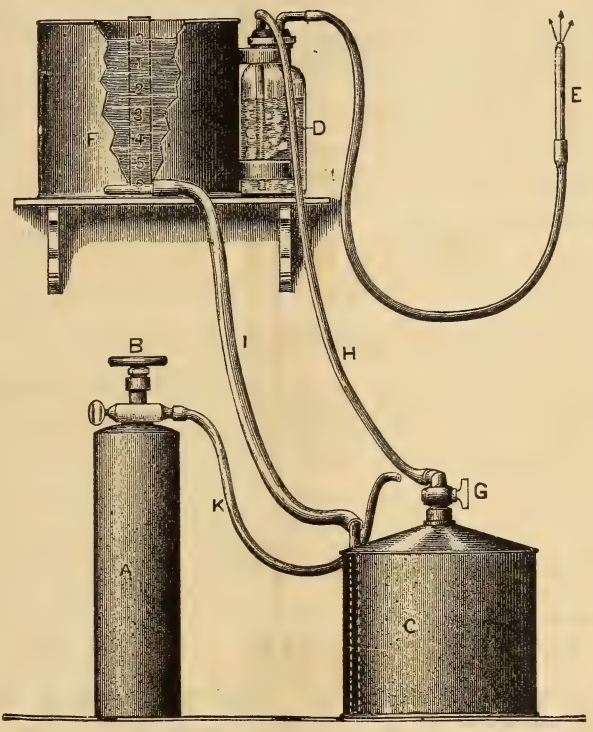
PURE OXYGEN

AND

APPARATUS FOR ITS THERAPEUTIC ADMINISTRATION



At the solicitation of a number of medical practitioners interested in oxygen treatment, we have devised apparatus for the therapeutic administration of this gas both by inhalation and by enema. We present an illustration of the latter. It is provided with a gauge by which the quantity of gas administered can be readily ascertained. We believe the apparatus we offer will be found to be the most convenient and economical device for the purpose on the market. We are prepared to supply Pure Oxygen Gas, or a mixture of Oxygen and Nitrous Oxide in definite proportions respectively of 20 per cent. and 40 per cent. of Nitrous Oxide, in cylinders of 40 or 100 gallons each. Full directions sent with each apparatus.

PRICES.

ENEMA APPARATUS	$12.00
INHALING APPARATUS	5.00
FORTY GALLON CYLINDER	6.00
FORTY GALLON CYLINDER FILLED	8.00
ONE HUNDRED GALLON CYLINDER	15.00
ONE HUNDRED GALLON CYLINDER FILLED	20.00

The Gas whether pure or mixed is supplied at the uniform price of 5 cents per gallon. The cost of the cylinders will be refunded on their return empty, with the valves in good condition.

THE S. S. WHITE DENTAL MFG. CO.,

PHILADELPHIA, NEW YORK, BOSTON, CHICAGO, BROOKLYN.

RABUTEAU'S DRAGEES OF IRON

Laureate of the Institute of France.—Prize in Therapeutics.

The studies made by the Physicians of the Hospitals have demonstrated that the **Genuine Dragees of Iron of Rabuteau** are superior to all other preparations of Iron in cases of *Chlorosis, Anæmia, Leucorrhœa, Debility, Exhaustion, Convalescence, Weakness of Children*, and the maladies caused by the Impoverishment and Alteration of the blood after periods of fatigue, watching, and excesses of any kind.

TAKE 4 TO 6 DRAGEES DAILY.

Rabuteau's Elixir of Iron is recommended to those persons who may be unable to swallow the Dragees. Dose —*A small wineglassful with meals.*

Rabuteau's Syrup of Iron is specially designed for children. Chalybeate medication, by means of **Rabuteau's Iron**, is the most economical and the most rational known to therapeutics.

No constipation, no diarrhœa, complete assimilation.

Take only the GENUINE IRON OF RABUTEAU of

CLIN & CO., Paris.

SOLUTION OF THE SALICYLATE OF SODA OF DOCTOR CLIN.

Laureate of the Paris Faculty of Medicine (MONTYON PRIZE).

Dr. Clin's Solution, always identical in its composition, and of an agreeable taste, permits the easy administration of *pure Salicylate of Soda*, and the variation of the dose in accordance with the indications presented.

"The *Salicylate of Soda* used by **Clin** is of perfect purity, "and is prepared with the greatest care; it is a medicament "in which we may have every confidence."

—*Paris Society of Medicine, Meeting of Feb. 8th, 1879.*

Clin's Solution, very exactly mixed, contains: 2 grammes of *Salicylate of Soda* per tablespoonful, 50 centigrammes of *Salicylate of Soda* per teaspoonful.

Paris—CLIN & CO.—Paris

AND BY ALL DRUGGISTS.

CAPSULES MATHEY-CAYLUS

WITH THIN ENVELOPE OF GLUTEN.

CONTAINING COPAIBA AND ESSENCE OF SANTAL; COPAIBA, CUBEBS, AND THE ESSENCE OF SANTAL; COPAIBA, IRON, AND THE ESSENCE OF SANTAL.

"The Mathey-Caylus Capsules, of the *Essence of* "*Santal*, associated with the Balsams, possess an incontesta- "ble efficaciousness, and are employed with the greatest "success for the rapid cure of old or recent *Discharges*, "*Gonorrhœa, Blenorrhœa, Leucorrhœa, Cystitis of the Neck*, "*Urethritis, Catarrh*, and other *diseases of the bladder*, together "with all affections of the *Urinary Passages*."

"Thanks to their thin envelope of *Gluten*, which is essen- "tially assimilable, the *Mathey-Caylus Capsules* are digested "by the most delicate persons, and never weary the stomach."

—*Gazette des Hopitaux de Paris.*

CLIN & CO., Paris,

AND OF ALL DRUGGISTS.

NEURALGIAS

PILLS OF DR. MOUSSETTE.

The **Moussette Pills** of aconitine and quinium, calm or cure *Gastralgia, Hemicrania, Headache, Sciatica*, and the most obstinate Neuralgias.

"The sedative action exerted by the **Moussette Pills** "upon the apparatus of the sanguineous circulation by the "intermediation of the vaso-motor nerves, indicates their "use in *neuralgias of the trigemini nerves*, (fifth pair), *con-* "*gestive neuralgias*, and *painful and inflammatory Rheumatismal* "*affections*."

"Aconitine produces marvelous effects in the treatment "of *facial neuralgias* when they are not symptomatic of "intracranial tumor."—*Society of Biology of Paris, Meeting* "*of the 28th February, 1880.*

DOSE—Take 3 to 6 pills during the twenty-four hours.

ACCEPT ONLY THE GENUINE MOUSSETTE PILLS OF

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.

E. FOUGERA & CO., New York,

Sole Agents for the United States for the above Preparations.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 1872, 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

☞ BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonary Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE., Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlets or other information, address

E. FOUGERA & CO., 30 North William St., New York,

Sole Agents for the above Preparations.

CELERINA

NERVE TONIC, STIMULANT AND ANTISPASMODIC.

FORMULA.—Every Fluid Drachm represents FIVE grains EACH—Celery, Coca, Kola, Viburnum and Aromatics.

INDICATIONS.—Loss of Nerve-Power (so usual with Lawyers, Preachers, Writers and Business Men), Impotency, Spermatorrhea, Nervous Headache, Neuralgia, Paralysis, Hysteria, Opium Habit, Inebriety, Dyspepsia, and ALL LANGUID conditions of the System.

Indispensable to restore a patient after alcoholic excess.

DOSE.—One or two Teaspoonfuls three or more times a day, as directed by the Physician.

LIQUID IRON-RIO

Palatable and easily assimilated. Does not produce Nausea, nor irritate the Stomach. Does not Cause Headache, nor Constipate. Does not Stain the Teeth. It is so Acceptable to the Stomach that its Use is Admissible when all other forms of Iron would be rejected. Being so Readily Assimilable, it only requires a small Dose.

Each Fluid Drachm contains ONE GRAIN of Iron in a Pleasant and Digestible Form.

DOSE.—One or more Teaspoonfuls as indicated, during or after meals.

S. H. KENNEDY'S

CONCENTRATED EXTRACT OF

PINUS CANADENSIS

DARK. **A NON-ALCOHOLIC LIQUID.** WHITE.

A MOST VALUABLE NON-IRRITATING MUCOUS ASTRINGENT.

INDICATIONS.—Albuminuria, Diarrhea, Dysentery, Night-Sweats, Hemorrhages, Profuse Expectoration, Catarrh, Sore Throat, Leucorrhea, and other Vaginal Diseases, Piles, Sores, Ulcers, Burns, Scalds, Gonorrhea, Gleet, Etc.

When Used as an Injection, to Avoid Staining of Linen, the WHITE Pinus should be used.

RECOMMENDED BY PROMINENT EUROPEAN AND AMERICAN PHYSICIANS.

SURGICAL AND ORTHOPÆDIC APPARATUS,
No. 18 North Eleventh Street,
Established 1866. **Philadelphia.**

An Important Communication
TO PHYSICIANS.

Thirteen years have now elapsed since the introduction of SCOTT'S EMULSION of PURE NORWEGIAN COD LIVER OIL with HYPOPHOSPHITES of LIME and SODA, since which time its growth and development have been very large, not only in this country but in South America, Great Britain and a large part of Continental Europe, and it has, in a very large degree, supplanted the Plain Cod Liver Oil. Its success is largely due to the happy combination of all its components, making a perfect chemical union, that will not separate for years, which we believe is not true of any other Cod Liver Oil preparation.

The innumerable reports from Physicians, of the brilliant results obtained justifies the statement that in almost every case where Cod Liver Oil is indicated, Scott's Emulsion is infinitely superior.

Physicians who have never tried this Emulsion, or who have been induced to try something else in its stead, will do us the favor to send for sample, and we know they will always use it in preference to plain Cod Liver Oil or any other preparation.

We also call your attention to the following preparations:

CHERRY-MALT PHOSPHITES.

A combination of the tonic principles of Prunus Virginiana, Malted Barley, Hypophosphites of Lime and Soda, and Fruit Juices. An elegant and efficient brain and nerve tonic.

BUCKTHORN CORDIAL (Rhamnus Frangula.)

Prepared from carefully selected German Buckthorn Bark, Juglans Bark, and Aromatics. The undoubted remedy for Habitual Constipation.

Be sure and send for samples of the above—delivered free.

SCOTT & BOWNE, 132 South Fifth Ave., New York.

A LETTER

RELATING TO

PIL: ANTISEPTIC AND ANTISEPTIC COMP.

The late eminent physician and most acute observer, DR. AUSTIN FLINT, Sr., has said: "Physicians are often consulted by patients, who, although far from being well, have no well-defined malady. They complain of langour, lassitude, want of buoyancy, aching of the limbs, and mental depression. They are wakeful during the night and enter upon their daily pursuits with a sense of fatigue."

'An investigation of the different organs of the body reveals no evidence of disease, the lungs, heart, and kidneys are sound. Some of the affections embraced in the posological catalogue may be discovered, yet the morbid condition is real.'" Hardly a practicing physician will read the above without recalling at once a number of cases with the identical symptoms as given by DR. FLINT. He will also remember how stubbornly such cases have resisted all the usual remedies, and dietetic precautions. Now what is the trouble and what the remedy? The trouble is simply chronic blood poisoning from Malaria, sewer gas, or what is far more likely from the products of a defective assimilation of food in the blood circulation. The remedy lies in first destroying these ptomainse, and for this there is no better or more quickly-acting remedy than Pil. Antiseptic, made by WARNER & Co., as any intelligent physician will see at a glance on noting its composition, or he will realize happily upon prescribing the remedy. This is not theory, but fact, tested by experience.—DR. F. S. GRANT.

PIL: ANTISEPTIC.

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ¼ gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic is prescribed with great advantage in cases of Dyspepsia attended with acid stomach and enfeebled digestion following excessive indulgence in eating or drinking. It is used with advantage in Rheumatism.

PIL: ANTISEPTIC COMP.

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ⅛ gr. Powd. Capsicum, 1-10 gr. Conc't Pepsin, 1 gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic Comp. are prescribed with great advantage in cases of Dyspepsia, Indigestion, and malassimilation of food.

WM. R. WARNER & CO.

PREPARATIONS SUPPLIED UPON PHYSICIANS' PRESCRIPTION, BY ALL LEADING DRUGGISTS.

PHILADELPHIA. NEW YORK.

McARTHUR'S SYRUP.

(SYR: HYPOPHOS: COMP: C. P. McARTHUR.)

Its use is indicated in Consumption and Tuberculosis, Diseases of the Chest, Chronic Cough, Throat Affections, General Debility, Brain Exhaustion, Impotence and Loss of Memory.

The point of primary importance in the use of the Hypophosphites is their *chemical* purity, but unfortunately they are too often adulterated.

So little seems to be generally known, even among the medical profession, with regard to the chemistry of the Hypophosphites, and the absolute necessity of CHEMICAL purity, that we call attention to this point.

One of the first effects produced by the use of our CHEMICALLY PURE Hypophosphites is a general increase of nervous energy, with a feeling of ease and comfort.

The second effect is an increase of appetite; digestion is improved, and the bowels become regular in their action, the quantity and color of the blood is increased, respiration is controlled, a better expansion of the chest is observed, cough improves, easy expectoration is produced, night perspiration diminishes, the face becomes fuller, the lips red, the nails and hair grow, and in children the teeth, showing the importance of the Hypophosphites on the organ of nutrition.

☞ Physicians when prescribing will please write thus:

℞ SYR: HYPOPHOS: COMP: McARTHUR. ONE BOTTLE.

As it is made *only for physicians* there are no printed wrappers or advertisements about the bottle.

Our pamphlet on the **CURABILITY AND TREATMENT OF CONSUMPTION,** sent free to physicians upon application.

We will send one bottle of McArthur's Syrup to any physician, without charge, who will pay the express charges on the same.

Mention this Journal. McARTHUR HYPOPHOSPHITE CO., BOSTON, Mass

Friedrichshall.

THE WELL-KNOWN APERIENT MINERAL WATER.

IMPORTANT NOTICE.

By reason of an improved method of caption, by which dilution is avoided, FRIEDRICHSHALL WATER will be found now to be of considerably greater strength and efficacy than heretofore

The ordinary dose is a large wineglassful (4 ounces), taken fasting. Most efficacious and more acceptable to the palate when heated or mixed with an equal quantity of very hot water.

"The most suitable aperient for prolonged use."—Prof. SEEGEN.

"After twenty years' use, I appreciate it as highly as ever."—Prof. VIRCHOW.

OF ALL DRUGGISTS AND MINERAL-WATER DEALERS.

YOU WILL FIND **BROMO-CAFFEINE** OF GREATEST SERVICE IN

OF ALL TYPES **NERVOUS HEADACHES** OF ALL TYPES

Headaches from Loss of Sleep, Physical Fatigue, Excessive Study, Mental Anxiety, Neurasthenia, Dysmenorrhœa, Pregnancy, or other Ovarian Irritation. Relieves Insomnia, and is very useful in Asthma, Whooping Cough and Nervous Cough. Prevents Tinnitis Aurium during the administration of Quinine. Cures Sea Sickness, Quiets the Restlessness of Alcoholism, Morphia Craving, &c. Relieves Anxiety and Promotes Sleep.

☞ **Avoid and discourage imitations and substitutions.** ☜

THERE IS A PEPSIN

WHICH IS UNIFORMLY ACTIVE, PERMANENT, AND RELIABLE,

IT IS "FAIRCHILD'S."

This Pepsin will not spoil, will not become soft and sticky in the vial, even if left long uncorked.

Fairchild's Pepsin will not "gum up" if dispensed in powders, plain, or with the drugs usually combined with pepsin.

Fairchild's is not a partial peptone, and has none of the well-known characteristics of peptone.

Fairchild's is the pioneer pepsin, it showed the way. It "got there" early.

Its activity has never been exaggerated.

All this time, whilst other manufacturers were still offering the high-dilution saccharated and amylated article, Fairchild's Pepsin was steadily making its way on its merit. Now, no one ventures to ask a hearing for these *placebo-pepsins.*

When physicians now prescribe "pepsin" they mean pepsin—not milk sugar, and pepsin.

All these years, Fairchild's Pepsin was always and everywhere found to do just what was claimed for it—in spite of the attitude, genuine or assumed, which held that all "claims" about pepsin must be taken with a liberal discount.

Every *bona fide* test demonstrated its reliability.

We have never found it necessary to explain or excuse any deficiency or inaction as due to "deteriorated" specimens.

Fairchild's will not disappoint the prescriber under any condition proper for pepsin.

WITH SUCH A RECORD Fairchild's Pepsin is a good one to stand by.

Four Books Learned in One Reading.

A Year's Work Done in Ten Days.

[From the Chaplain of Exeter College, and Houghton Syriac Prizeman, Oxford.]

COLL. EXON. OXON., Sept., 1888.

DEAR SIR: In April, 1885, while thinking of taking orders in September, I suddenly received notice that my ordination examination would be held in a fortnight. I had only *ten* (10) days in which to prepare for the Exam. I should recommend a *year's* preparation in the case of anyone so utterly unprepared as I was; but your *System had so strengthened my natural memory*, that I was able to remember and give the gist of any *book after reading it once.* I therefore *read* Lightfoot, Proctor, Harold Browne, Mosheim, &c., &c., *once*, and was *successful* in *every one* of the *nine* papers. The present Bishop of Edinburg knows the facts.

Faithfully yours,

[REV.] JAMES MIDDLETON MACDONALD, [M.A.]

ANOTHER STRANGE THING.

---o---

Of all the new editions of well known Physicians' Visiting Lists which we have seen this year, not one but looks poorer and meaner than it did a year ago!

Why should this be? There is not much profit in these books; but it does not seem good policy to try to make it bigger by making the book poorer. At least we think so here; and so the POCKET RECORD which has been issued from this office for TWENTY THREE YEARS will be issued this year better than it ever was before. All the old, and approved features are retained, and some new ones are introduced. Special attention has been paid to the paper, printing, and binding. The 30 Patient books are printed with dates, or without them. This, because it is clear that many physicians prefer books with dates. Our subscribers will be safe in ordering, and let them do it now.

PRICE.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,
36th and Woodland Ave., Phila.

WANTED PHYSICIAN to take charge of a large Sanitarium and one who can invest $5,000 to $10,000 in order to be properly identified with the interests of the institution. DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

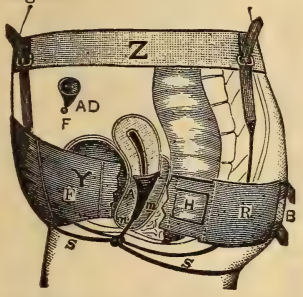
STAUFER'S

UTERINE SUPPORTER

HARD RUBBER. SPRING STEM.

This supporter, as now made, is the result of seventeen years' experience in manufacturing instruments for the treatment of displacements of the womb, aided by the suggestions of a large number of practitioners who have used these well-known supporters in the past.

The construction of the instrument shown in the cut is such that the cup inclines forward, and this inclination, together with the curve in the stem adapts it to the axis of the uterus and vagina.



There is a Coil-spring in the tube at *m*, which prevents shock to the womb when the patient sits down.

The instrument is held in position by means of a belt (Z or Y) and elastic cords (S S). One form of belt (Z) surrounds the waist; another (Y) is made like an abdominal supporter. The belts are made of 3-ply, fine cotton material, with elastic hip-straps, and buckle at the back.

Self-Sustaining Supporter.—The supporter may also be used without a belt, when no great bodily exertion calls for the latter. A little stem (F) is screwed on the cup (A), instead of the longer stem (*n*), as shown in the figure A D, and the instrument becomes self-sustaining.

The cup is made in sizes ranging from 1¼ inches to 2¼ inches in diameter, the difference from one size to another being ⅛ inch. The size most frequently used is 1¾ inches across the cup.

SELECTION In ordering, give exact measure around the hips, just below crest of ilium, and the width of cup on top, as nearly as this can be estimated.

EXCHANGE Dr. Staufer will exchange one size of the supporter for another, if desired. PROVIDED the request is made within a reasonable time, and when the *three rubber parts* are returned in good condition.

THE BELTS ARE NOT EXCHANGED.

Because they are apt to show the effect of use, and there is no trouble about getting a good fit, if the correct measure is sent.

PRICE

The instrument complete, with belt Z, costs $4.00
" " " " " Y, " 5.00

SEND MONEY WITH ORDER.

COLDEN'S LIQUID BEEF TONIC.

ORIGINAL LABEL:
"Colden's Liebig's Liquid Extract of Beef and Tonic Invigorator."

An Invaluable Aid in the Treatment of all Cases of Debility.

☞ ESTABLISHED 15 YEARS. ☞ ENDORSED BY SCORES OF PHYSICIANS. ☞ BEWARE OF IMITATIONS.

☞ ESSENTIALLY DIFFERENT FROM ALL OTHER BEEF TONICS.

COLDEN'S LIQUID BEEF TONIC consists of the Extract of Beef (by Baron Liebig's process), spirit rendered non-injurious to the most delicate stomach by extraction of Fusel Oil, Soluble Citrate of Iron, Cinchona, Gentian, and simple aromatics. An official analysis of this preparation by the eminent chemist, ARTHUR HILL HASSALL, M.D., F.R.S., and an endorsement of by Sir ERASMUS WILSON, F.R.S., is printed on the label of each bottle.

In the treatment of all cases of Debility, Convalescence from severe illness, Anæmia, Malarial Fever, Chlorosis, Incipient Consumption, Lack of Nerve Tone, and of the Alcohol and Opium Habits, and all maladies requiring a Tonic Nutrient, it is superior to all other preparations.

It acts directly on the sentient gastric nerves, stimulating the follicles to secretion, and gives to weakened individuals that first prerequisite to improvement, an appetite.—By the urgent request of several eminent members of the medical profession, I have added to each wineglassful of this preparation two grains of SOLUBLE CITRATE OF IRON, and which is designated on the label WITH IRON, "No. 1;" while the same preparation, WITHOUT IRON, is designated on the label as "No. 2."

☞ *I will, upon application, send a sample bottle of* COLDEN'S LIQUID BEEF TONIC *to any physician in regular standing. Please ask your Dispensing Druggist (if he has not already a supply) to order it. In prescribing this preparation physicians should be particular to mention* "COLDEN'S," *viz.,* "EXT. CARNIS FL. COMP. (COLDEN)." *It is put up in pint bottles, and* CAN BE HAD OF WHOLESALE AND RETAIL DRUGGISTS GENERALLY THROUGHOUT THE UNITED STATES.

C. N. CRITTENTON, Sole Agent, 115 Fulton Street, New York.

GLENN'S SULPHUR SOAP.

All physicians know the great value of the local use of Sulphur in the TREATMENT OF DISEASES OF THE SKIN. GLENN'S SULPHUR SOAP is the ORIGINAL and BEST combination of its kind, and the one now generally used. For sale by all Druggists at 25 cents a cake, or three cakes for 60 cents. Beware of counterfeits.

CONSTANTINE'S PINE TAR SOAP.

BY FAR THE BEST TAR SOAP MADE. Has been on trial among physicians for very many years as a toilet soap and healing agent, and its superior virtues have been unanimously conceded in ALL CASES WHERE THE USE OF TAR IS INDICATED.

Unsolicited expressions of its excellence have been received from the Medical Faculty generally. None genuine unless stamped "A. A. Constantine's Persian Healing Pine Tar Soap." For sale by all Druggists.

Wholesale Depot, C. N. CRITTENTON, 115 Fulton Street, New York.

Please mention this Journal. ☞ Samples of above Soaps SENT FREE on application to any physician enclosing card.

MEDICAL AND SURGICAL REPORTER

P.O. Box 843 PHILADELPHIA

DR. WILLIAM A. HAMMOND'S SANITARIUM

—FOR—

DISEASES OF THE NERVOUS SYSTEM,

WASHINGTON, D. C.

DR. WILLIAM A. HAMMOND announces to the medical profession that he has returned from New York to Washington, D. C., where he has established, in a building especially erected for the purpose, a *Sanitarium* for the treatment of mild and curable cases of mental derangement, diseases of the nervous system generally, cases of the morphia and chloral habits, and such other affections as may properly be treated by the remedial agencies under his control. His experience during many years has convinced him that most diseases embraced within the above-named classes can be managed much more successfully in an institution of this kind, under the constant supervision of the physician and with the aid of means not otherwise at command, than when the patients are seen by their medical advisers at intervals of several hours or days.

The *Sanitarium*, which has been constructed under the superintendence of A. B. Mullett, Esq., late architect of the United States Treasury department, and is situated on Columbia Heights, at the corner of Fourteenth Street and Sheridan Avenue. The position is the highest in the immediate vicinity of Washington, the soil is dry, and all the surroundings are free from noxious influences. It is readily reached by the Fourteenth Street Railway, the cars of which run to the doors The building is very large, and as perfect in structure and arrangements as is possible from a knowledge of sanitary science and of the requirements of such an institution. It accommodates about thirty patients. So far as the rooms, table, etc., are concerned, they are equal to such as exist in the best hotels of our large cities. Electricity in all its forms; baths, douches, massage, inhalations, nursing, etc., are provided as may be required by patients, in addition to such other medical treatment as may be deemed advisable.

A large *Solarium* for sun-baths and exercise in cold or inclement weather and heated with steam in winter, is constructed on the top of the main building.

Each patient is thoroughly examined by Dr. Hammond and receives his daily personal attention, while Dr. E. L. Tompkins, a physician of ample hospital experience and of tried executive ability, resides in the institution and has, under Dr. Hammond, the immediate superintendence.

The *Sanitarium* is now opened for the reception of patients.

For further information Dr. Hammond can be addressed at The Sanitarium, Fourteenth Street and Sheridan Avenue, Washington, D. C.

TO EACH SUBSCRIBER.

---o---

Dear Doctor:

I beg your co-operation in endeavoring to get all the subscribers to the MEDICAL AND SURGICAL REPORTER to cordially accept a condition usual with first-class periodicals, that is, that subscriptions shall be paid in advance. There are still some of our subscribers who have accounts unsettled for the year 1888, and they are urged to pay this amount and the price for the year 1889 as soon as possible.

The evidences of approval of the REPORTER by medical men are multiplying. The subscription list is growing larger, and it is hoped that all who are now subscribers will long continue their patronage, and that they will heartily support the publisher in endeavoring to maintain those principles of business which experience shows to be best for all, not only for the publishers but for also the subscribers.

SO SEND WHAT YOU OWE, SOON.

Make all checks or money-orders payable to

CHARLES W. DULLES.

LEGS and ARMS with RUBBER FEET and HANDS

(MARKS' PATENTS.)

Indorsed by the United States Government, the Industrial Exhibition Commissioners of New York, Philadelphia, Atlanta, New Orleans, etc, the eminent surgeons in the country, the press, and over 9,000 men, women, and children who wear them, residing in all parts of the world.

The Rubber Foot and Hand possess the most natural appearance, the greatest durability and comfort of all artificial limbs. Vast numbers of mutilated men and women are, by the use of rubber feet and hands, enabled to mingle with the rest of the world without betraying their loss or experience great inconvenience. Farmers, mechanics, professionals, and even athletes, who have lost one or more of their limbs, are enabled to resume their vocations by the use of these remarkable inventions.

MR. A. A. MARKS: ITHACA, TOMPKINS CO., N.Y., Jan. 15, 1888.

DEAR SIR: Rubber feet are the wonders of the world. I have challenged every maker in the world to produce a man that has a pair of artificial feet to walk with me. I can walk a mile in thirteen minutes, and not hurry myself any. I do not take a back seat for any unprofessional with two good natural feet, in a one mile walk. I have the pleasure of announcing that my record in walking professionally is unequaled in the world by any one with artificial legs. THOMAS CLEARY.

By a copyright formula, furnished by us on request, applicants can supply us with all the data necessary to secure fit and satisfactory results, while they remain at home. One-half the legs and arms furnished by us are made from measurements and profiles, without our seeing the wearer. This new method is a great convenience for those living at a distance. Fit always guaranteed.

A treatise of 400 pages, and nearly 200 illustrations, and nearly a thousand endorsements and testimonals, sent to those needing artificial legs or arms, who will give a description of their case. The same will be sent to physicians and surgeons free of charge. Address,

A. A. MARKS, 701 Broadway, New York City.

Clinical and practical instruction in the medical and surgical specialties is afforded to physicians only, during the entire year. The College has well-fitted laboratories of pathology, miscroscopy, anatomy, surgery, and electro-therapeutics.

In addition to the clinical facilities of the dispensary, the professors utilize, for purposes of instruction, their services in the Philadelphia, Pennsylvania, Wills, Howard, Episcopal, Presbyterian, German, St. Mary's and, St. Christopher's Hospitals.

The Fee for each branch, for six consecutive weeks from date of issue, is $15.00. Any number of branches may be taken. General Ticket for the thirteen clinical courses, for six consecutive weeks, $100.00. Ticket for Summer course, from July 2d to September 15th, $60.00. One month, Summer course, $25.00. One branch, Summer course, $10.00.

L. W. STEINBACH, M.D. Secretary,
At the College Building, N. W. Cor. Broad and Lombard Streets, Philadelphia.

THE NEW HYPNOTIC
SULFONAL-BAYER.

SULFONAL was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

SULFONAL (Diæthylsulfondimethylmethan) is in the form of colorless prisms, odorless, and tasteless, melting at 125.5° C. (258° F.) and has the composition $(C H_3)_2=C=(C_2 H_5 SO_2)_2$. It is slightly soluble in cold water, but easily soluble in hot water or alcohol.

SULFONAL was first examined as to its physiological and pathological effects by Prof. A. Kast, of Freiburg University, and its hypnotic action was discovered and studied by him.

Since then SULFONAL has been the subject of numerous trials and experiments by many eminent and experienced physicians. Their testimony is unanimously favorable, and the conclusions reached by them are as follows:

SULFONAL is a prompt and reliable hypnotic, which in proper doses, produces quiet, natural sleep, lasting a number of hours.

SULFONAL has no unfavorable effects on the heart and the circulation, nor on the temperature, the pulse, or the respiration.

SULFONAL produces no disagreeable secondary symptoms; the patients with very few exceptions awake from their sleep feeling strong and greatly refreshed.

SULFONAL does not interfere with the process of digestion.

SULFONAL is a hypnotic, and not a narcotic; it acts by giving rest to the cells of the cerebral cortex, thereby causing sleep.

SULFONAL does not create an unconquerable desire for its repeated use; there is no danger of a SULFONAL-habit Neither is it necessary to increase the dose after long-continued use.

SULFONAL is best administered at supper-time, dissolved in hot liquids, *e. g.*, a bowl of soup or broth, a cup of milk, tea, coffee, cocoa, etc.

These points will be found to be fully exhibited in the series of contributions contained in our pamphlet, which will be mailed on application.

SULFONAL-BAYER is supplied by us in half-ounce and one-ounce vials.

We prepare 5-grain and 15-grain Tablets of Sulfonal-Bayer. The tablet form is admirably adapted to the purpose of administering this drug, as when they are placed in the liquids, they disintegrate and are thus received into the system.

We also put up Sulfonal-Bayer in the form of our Soluble Pills, containing five grains each.

THE NEW ANTIPYRETIC
PHENACETINE-BAYER.

Phenacetine-Bayer (Para-Acetphenetidine) is a white, glossy, crystalline powder, perfectly tasteless, melting at 135° C.=307° F and has the composition $C_6 H_4 <^{O.C_2H_5}_{NH(CO-CH_3)}$.

It is slightly soluble in water, a little more soluble in glycerine, but most freely in alcohol.

Phenacetine-Bayer was first prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, and is of absolute purity and uniform quality.

Summarizing the superiority of Phenacetine-Bayer over other antipyretics and antineuralgics, the following conclusions are formed:

1. ***Phenacetine-Bayer is an efficacious antipyretic.***
2. ***It does not develop any disagreeable or noxious after-effects.***
3. ***The dose required is half that of Antipyrine.***
4. ***It is perfectly tasteless.***
5. ***On account of its innocuousness and tastelessness, it is a valuable antipyretic both in adults and in children.***
6. ***Phenacetine-Bayer is an important antineuralgic; its effect is more energetic than that of Antipyrine and does not cause lassitude or any other disagreeble symptoms.***

Our pamphlet on Phenacetine-Bayer, containing the valuable testimony of eminent physicians will be mailed on application.

We offer Phenacetine-Bayer in one-ounce vials, or in the form of our Soluble Pills of the strength of two and four grains to each pill.

W. H. SCHIEFFELIN & CO.,

170 & 172 WILLIAMS STREET, NEW YORK,

SOLE LICENSEES AND SOLE AGENTS FOR THE UNITED STATES.

A NEW USE

FOR

Liquid Peptonoids.

Successfully used in Dissolving the False Membrane in Diphtheria.

A Physician writes: "In an experience of over thirty years I have never used anything to equal your LIQUID PEPTONOIDS as a local application with a spray. It will dissolve the membrane and destroy the diphtheritic odor in less than twenty-four hours. I use the LIQUID PEPTONOIDS full strength as a spray, two or three times a day, in bad cases."

Used successfully by another physician in two desperate cases:

"I was induced to try LIQUID PEPTONOIDS in two very desperate cases of DIPHTHERIA. I think I never saw throats more heavily coated with exudate than were these, and I think I never saw it more rapidly disappear than in these cases, by frequent spraying with your LIQUID PEPTONOIDS."

LIQUID PEPTONOIDS can be taken by patients unable to ingest food in any other form. In *Dyspepsia* and *loss of appetite* its effects are positive, its digestive properties assisting in the digestion of food taken and its peptogenic properties quickly stimulating the natural digestive secretions of the stomach.

Pancrobilin.

Prepared (in both Liquid and Pill form) from Extract of Pancreas and Bile.

This preparation is designed expressly to increase the digestion and absorption of fats.

We believe that the fat-digesting properties of pancreatine and bile are inseparable, and that without their union in the intestinal tract but little, if any, fat would be digested and absorbed.

PANCROBILIN will be found of great service in *Phthisis and other wasting diseases, Nervous Prostration, Constipation, Inanition, Malnutrition, Intestinal Indigestion,* and wherever there is a failure to assimilate fats.

If the skin is first wet with LIQUID PANCROBILIN, the inunction of oils will be greatly facilitated.

LIQUID PANCROBILIN is put up in pound bottles.

PILL PANCROBILIN is put up in bottles holding 100 pills. The coating of the pills will resist acid digestion when given as directed, but will be quickly dissolved in the alkaline secretions of the duodenum.

Phospho-Caffein Comp.

(*Granular Effervescing.*)

Formula for each dessertspoonful:—

Caffein.
Acidi Phosphorici, ää, gr. ss.
Antipyrin.
Ext. Apii. Grav. dulc. (*Celery*), *ää gr.* .
Sodii Bromidi, gr. v.

The satisfactory results produced by PHOSPHO-CAFFEIN COMP. in *Headaches, Neuralgia, Insomnia, Neurasthenia, and general Nervous Irritability,* are not due to the effect of any one ingredient, but to the happy effect of the combination. A thorough series of comparative tests have demonstrated the superiority of the above formula over any other in the market.

REED & CARNRICK, New York.

RABUTEAU'S DRAGEES OF IRON

Laureate of the Institute of France.—Prize in Therapeutics.

The studies made by the Physicians of the Hospitals have demonstrated that the **Genuine Dragees of Iron of Rabuteau** are superior to all other preparations of Iron in cases of *Chlorosis, Anæmia, Leucorrhœa, Debility, Exhaustion, Convalescence, Weakness of Children*, and the maladies caused by the Impoverishment and Alteration of the blood after periods of fatigue, watching, and excesses of any kind.

TAKE 4 TO 6 DRAGEES DAILY.

Rabuteau's Elixir of Iron is recommended to those persons who may be unable to swallow the Dragees. Dose —*A small wineglassful with meals.*

Rabuteau's Syrup of Iron is specially designed for children: Chalybeate medication, by means of **Rabuteau's Iron,** is the most economical and the most rational known to therapeutics.

No constipation, no diarrhœa, complete assimilation.

Take only the GENUINE IRON OF RABUTEAU of

CLIN & CO., Paris.

SOLUTION OF

THE SALICYLATE OF SODA OF DOCTOR CLIN.

Laureate of the Paris Faculty of Medicine

(MONTYON PRIZE).

Dr. Clin's Solution, always identical in its composition, and of an agreeable taste, permits the easy administration of *pure Salicylate of Soda*, and the variation of the dose in accordance with the indications presented.

"The *Salicylate of Soda* used by **Clin** is of perfect purity, "and is prepared with the greatest care; it is a medicament "in which we may have every confidence."

—*Paris Society of Medicine, Meeting of Feb. 8th, 1879.*

Clin's Solution, very exactly mixed, contains: 2 grammes of *Salicylate of Soda* per tablespoonful, 50 centigrammes of *Salicylate of Soda* per teaspoonful.

NEURALGIAS

PILLS OF DR. MOUSSETTE.

The **Moussette Pills** of aconitine and quinium, calm or cure *Gastralgia, Hemicrania, Headache, Sciatica*, and the most obstinate Neuralgias.

"The sedative action exerted by the **Moussette Pills** "upon the apparatus of the sanguineous circulation by the "intermediation of the vaso-motor nerves, indicates their "use in *neuralgias of the trigemini nerves*, (fifth pair), *con-* "*gestive neuralgias*, and *painful and inflammatory Rheumatismal* "*affections*."

"Aconitine produces marvelous effects in the treatment "of *facial neuralgias* when they are not symptomatic of "intracranial tumor."—*Society of Biology of Paris, Meeting* "*of the 28th February, 1880.*

DOSE—Take 3 to 6 pills during the twenty-four hours.

ACCEPT ONLY THE GENUINE MOUSSETTE PILLS OF

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.

E. FOUGERA & CO., New York,

Sole Agents for the United States for the above Preparations.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 1872, 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonary Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE., Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlets or other information, address

Sole Agents for the above Preparations.

ANOTHER STRANGE THING.

---o---

Of all the new editions of well known Physicians' Visiting Lists which we have seen this year, not one but looks poorer and meaner than it did a year ago!

Why should this be? There is not much profit in these books; but it does not seem good policy to try to make it bigger by making the book poorer. At least we think so here; and so the POCKET RECORD which has been issued from this office for TWENTY THREE YEARS will be issued this year better than it ever was before. All the old, and approved features are retained, and some new ones are introduced. Special attention has been paid to the paper, printing, and binding. The 30 Patient books are printed with dates, or without them. This, because it is clear that many physicians prefer books with dates. Our subscribers will be safe in ordering, and let them do it now.

PRICE.

Anyway, let us send you our complimentary portfolio of baby pictures—they are beauties. Sample of Lactated Food mailed to any physician unacquainted with its merits.

WELLS & RICHARDSON CO., Proprietors

BURLINGTON, VT.

THERE IS A PEPSIN

WHICH IS UNIFORMLY ACTIVE, PERMANENT, AND RELIABLE,

IT IS "FAIRCHILD'S."

This Pepsin will not spoil, will not become soft and sticky in the vial, even if left long uncorked.

Fairchild's Pepsin will not "gum up" if dispensed in powders, plain, or with the drugs usually combined with pepsin.

Fairchild's is not a partial peptone, and has none of the well-known characteristics of peptone.

Fairchild's is the pioneer pepsin, it showed the way. It "got there" early.

Its activity has never been exaggerated.

All this time, whilst other manufacturers were still offering the high-dilution saccharated and amylated article, Fairchild's Pepsin was steadily making its way on its merit. Now, no one ventures to ask a hearing for these *placebo-pepsins.*

When physicians now prescribe "pepsin" they mean pepsin—not milk sugar, and pepsin.

All these years, Fairchild's Pepsin was always and everywhere found to do just what was claimed for it—in spite of the attitude, genuine or assumed, which held that all "claims" about pepsin must be taken with a liberal discount.

Every *bona fide* test demonstrated its reliability.

We have never found it necessary to explain or excuse any deficiency or inaction as due to "deteriorated" specimens.

Fairchild's will not disappoint the prescriber under any condition proper for pepsin.

WITH SUCH A RECORD Fairchild's Pepsin is a good one to stand by.

TO EACH SUBSCRIBER.

---o---

Dear Doctor:

I beg your co-operation in endeavoring to get all the subscribers to the MEDICAL AND SURGICAL REPORTER to cordially accept a condition usual with first-class periodicals, that is, that subscriptions shall be paid in advance. There are still some of our subscribers who have accounts unsettled for the year 1888, and they are urged to pay this amount and the price for the year 1889 as soon as possible.

The evidences of approval of the REPORTER by medical men are multiplying. The subscription list is growing larger, and it is hoped that all who are now subscribers will long continue their patronage, and that they will heartily support the publisher in endeavoring to maintain those principles of business which experience shows to be best for all, not only for the publishers but for also the subscribers.

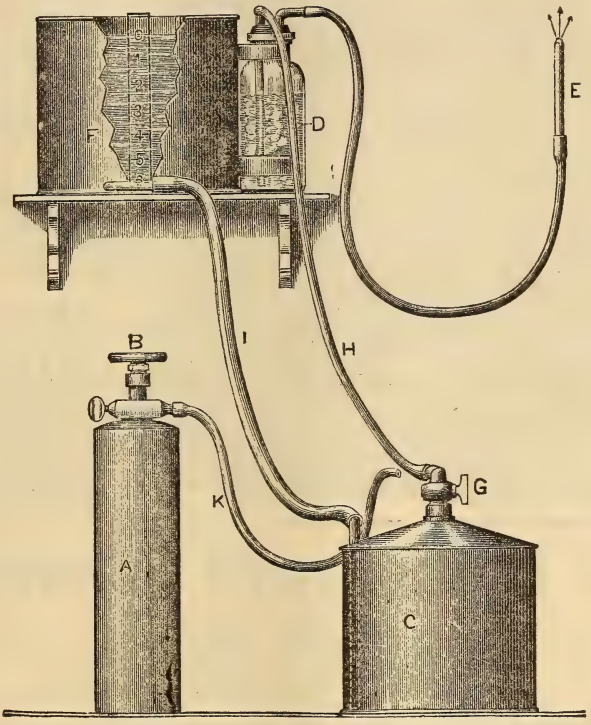
PURE OXYGEN

AND

APPARATUS FOR ITS THERAPEUTIC ADMINISTRATION



At the solicitation of a number of medical practitioners interested in oxygen treatment, we have devised apparatus for the therapeutic administration of this gas both by inhalation and by enema. We present an illustration of the latter. It is provided with a gauge by which the quantity of gas administered can be readily ascertained. We believe the apparatus we offer will be found to be the most convenient and economical device for the purpose on the market. We are prepared to supply Pure Oxygen Gas, or a mixture of Oxygen and Nitrous Oxide in definite proportions respectively of 20 per cent. and 40 per cent. of Nitrous Oxide, in cylinders of 40 or 100 gallons each. Full directions sent with each apparatus.

PRICES.

ENEMA APPARATUS	$12.00
INHALING APPARATUS	5.00
FORTY GALLON CYLINDER	6.00
FORTY GALLON CYLINDER FILLED	8.00
ONE HUNDRED GALLON CYLINDER	15.00
ONE HUNDRED GALLON CYLINDER FILLED	20.00

The Gas whether pure or mixed is supplied at the uniform price of 5 cents per gallon. The cost of the cylinders will be refunded on their return empty, with the valves in good condition.

ANTISEPTIC DRAINAGE TUBES.—Glass.

These Tubes have large holes, one-half inch apart, arranged alternately on opposite sides.
They are carefully finished, especial care being taken to make them smooth.
In addition to the drainage-holes, each tube has at one end two smaller holes for the insertion of Safety-Pin, through which it is prevented slipping into the wound.

FURNISHED IN SEVEN SIZES.

No. 1, $1 25 per doz. No. 4, $1 55 per doz.
No. 2, 1.25 " No. 5, 1.70 "
No. 3, 1.40 " No. 6, 1.90 "
No. 7, $2.10 per dozen.

RAW CAT-GUT. I put this up in coils of 10 feet, four difierent sizes, Nos. 1, 2, 3, 4 (4 is thickest). Nos. 2 and 3 are the most useful sizes. **No. 1 Coil, 10 Cents; No. 2 Coil, 12 Cents; No. 3 Coil, 14 Cents; No. 4 Coil, 16 Cents.** Full directions with each coil for making it absolutely aseptic.

WILLIAM SNOWDEN,

Manufacturer, Importer and Exporter of Surgical Instruments,

No. 7 SOUTH ELEVENTH STREET, PHILADELPHIA.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

ST. LOUIS, MO.

An Important Communication
TO PHYSICIANS.

Thirteen years have now elapsed since the introduction of SCOTT'S EMULSION of PURE NORWEGIAN COD LIVER OIL with HYPOPHOSPHITES of LIME and SODA, since which time its growth and development have been very large, not only in this country but in South America, Great Britain and a large part of Continental Europe, and it has, in a very large degree, supplanted the Plain Cod Liver Oil. Its success is largely due to the happy combination of all its components, making a perfect chemical union, that will not separate for years, which we believe is not true of any other Cod Liver Oil preparation.

The innumerable reports from Physicians, of the brilliant results obtained justifies the statement that in almost every case where Cod Liver Oil is indicated, Scott's Emulsion is infinitely superior.

Physicians who have never tried this Emulsion, or who have been induced to try something else in its stead, will do us the favor to send for sample, and we know they will always use it in preference to plain Cod Liver Oil or any other preparation.

We also call your attention to the following preparations:

CHERRY-MALT PHOSPHITES.

A combination of the tonic principles of Prunus Virginiana, Malted Barley, Hypophosphites of Lime and Soda, and Fruit Juices. An elegant and efficient brain and nerve tonic.

BUCKTHORN CORDIAL (Rhamnus Frangula.)

Prepared from carefully selected German Buckthorn Bark, Juglans Bark, and Aromatics. The undoubted remedy for Habitual Constipation.

Be sure and send for samples of the above—delivered free.

SCOTT & BOWNE, 132 South Fifth Ave., New York

Are meeting with the same success. Send for Catalogue.

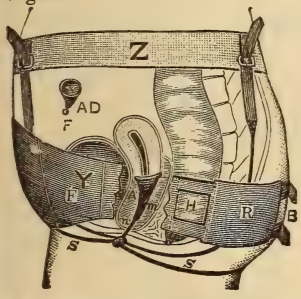
STAUFER'S

UTERINE SUPPORTER

HARD RUBBER. SPRING STEM.

This supporter, as now made, is the result of seventeen years' experience in manufacturing instruments for the treatment of displacements of the womb, aided by the suggestions of a large number of practitioners who have used these well-known supporters in the past.

The construction of the instrument shown in the cut is such that the cup inclines forward, and this inclination, together with the curve in the stem adapts it to the axis of the uterus and vagina.



There is a Coil-spring in the tube at *m*, which prevents shock to the womb when the patient sits down.

The instrument is held in position by means of a belt (Z or Y) and elastic cords (S S). One form of belt (Z) surrounds the waist; another (Y) is made like an abdominal supporter. The belts are made of 3-ply, fine cotton material, with elastic hip-straps, and buckle at the back.

Self-Sustaining Supporter.—The supporter may also be used without a belt, when no great bodily exertion calls for the latter. A little stem (F) is screwed on the cup (A), instead of the longer stem (*n*), as shown in the figure A D, and the instrument becomes self-sustaining.

The cup is made in sizes ranging from $1\frac{1}{4}$ inches to $2\frac{1}{4}$ inches in diameter, the difference from one size to another being $\frac{1}{8}$ inch. The size most frequently used is $1\frac{3}{4}$ inches across the cup.

SELECTION In ordering, give exact measure around the hips, just below crest of ilium, and the width of cup on top, as nearly as this can be estimated.

EXCHANGE Dr. Staufer will exchange one size of the supporter for another, if desired. PROVIDED the request is made within a reasonable time, and when the *three rubber parts* are returned in good condition.

THE BELTS ARE NOT EXCHANGED.

Because they are apt to show the effect of use, and there is no trouble about getting a good fit, if the correct measure is sent.

PRICE

The instrument complete, with belt Z, costs	$4.00
" " " " " Y, "	5.00

ALETRIS CORDIAL

UTERINE TONIC AND RESTORATIVE.

Prepared from the Aletris Farinosa or True Unicorn and Aromatics.

INDICATIONS.

Amenorrhea, Dysmenorrhea, Leucorrhea, Prolapsus Uteri, Sterility, to Prevent Miscarriage, Etc.

DOSE:—ONE TEASPOONFUL THREE OR FOUR TIMES A DAY.

UNRIVALED AS A UTERINE TONIC IN IRREGULAR, PAINFUL, SUPPRESSED AND EXCESSIVE MENSTRUATION.

It Restores Normal Action to the Uterus, and Imparts Vigor to the Entire Uterine System.

☞Where women have miscarried during previous pregnancies, or in any case where miscarriage is feared, the ALETRIS CORDIAL is indicated, and should be continuously administered during entire gestation.

CHAS. CLAY, M. R. C. S., Manor House, Dewsbury, England, says:—I find Aletris Cordial (Rio) is of great service in threatened miscarriage.

FRANCIS E. CANE, L. R. C. S., &c., Leeds, England, says:—I have tried the Aletris Cordial (Rio) in two cases of long standing dysmenorrhea, with excellent results. One of these patients has spent a week in bed every month for two years. After all the usual remedies, I put her on Aletris Cordial, and for the last two periods she has been out and about all the time.

L. M. WATSON, M. D., Delhi, Ills., says:—I have used Aletris Cordial (Rio) in cases of dysmenorrhea, suppressed menses and threatened miscarriage, and also, combined with Celerina, as a tonic after confinement, with the happiest results, and now I am using it on a case of leucorrhea, with injections of S. H. Kennedy's Extract of Pinus Canadensis, and it is acting like a charm.

P. H. OWEN, M. D., Morganville, Ala., says:—I have prescribed Aletris Cordial (Rio) in several cases with the most satisfactory results, and regard it as the best uterine tonic I have met with in a professional experience of over twenty-five years. In cases of threatened miscarriage it acts like a charm. Would recommend its continuous administration in all cases when there is any indication of miscarriage.

Dr. W. BERTHELOT, Santander, Spain, says:—I have tried the Aletris Cordial (Rio), and it has seemed to me to be useful, especially in cases of dysmenorrhea.

Dr. RASQUINET, Jupile, near Liege, Belgium, says:—I tried Aletris Cordial (Rio) in the case of a woman who had had several miscarriages at the end of five months, and who is now again pregnant, having reached the seventh month, thanks to Aletris Cordial.

R. REECE, M. R. C. S., Walton-on-Thames, England, says:—Aletris Cordial (Rio) in painful menstruation is most valuable. A wife of a minister suffered much, and had had three miscarriages I prescribed Aletris Cordial. She has for the first time, gone her full time, and was safely confined with a male child.

J. T. COLLIER, M. D., Brooks, Me., says:—I have used your Aletris Cordial (Rio) in cases of females at the menopause. Consider it one of the finest remedies for these cases.

Dr. GORDILLON, St. Amand, France, says: I have tried the Aletris Cordial (Rio) in a case of dysmenorrhea. The result I obtained from the use of your preparation was excellent, better than I had obtained in the same patient by prescribing the usual remedies employed in such cases.

W. F. TOOMBS, M. D., Morrillton, Ark., says:—I have used a great deal of your Aletris Cordial (Rio) and I find it all you claim for it in amenorrhea, dysmenorrhea, metritis, leucorrhea; I don't think it has an equal. I have used it in two cases of threatened miscarriage and the trouble was obviated. For a general Uterine Tonic I know of nothing superior.

R. D. PATTERSON, L. R. C. S. &c., Medical Officer, Caledon Dispensary, Co. Tyrone, Ireland, says:—I have very great pleasure in testifying to the very high opinion I hold of Aletris Cordial (Rio) in threatened miscarriage.

BUFFALO LITHIA WATER

IN THE

Uric Acid Diathesis, Bright's Disease of the Kidneys, Chronic Inflammation of the Bladder, &c.

Dr. THOMAS H. BUCKLER, of Paris (formerly of Baltimore), SUGGESTER OF LITHIA as a Solvent for URIC ACID.

"Nothing I could say would add to the **WELL-KNOWN REPUTATION OF THE BUFFALO LITHIA WATER. I HAVE FREQUENTLY USED IT WITH GOOD RESULTS IN URIC ACID DIATHESIS, RHEUMATISM AND GOUT,** and with this object I have ordered it to Europe from Coleman & Rogers, of Baltimore. Lithia is in no form so valuable as where it exists in the Carbonate (the form in which it is found in the **BUFFALO LITHIA WATER**), Nature's mode of solution and division in water which has passed through Lepedolite and Spondumine Mineral formation."

Dr. WM. A. HAMMOND, of New York, Surgeon-General U. S. Army (Retired), Professor of Diseases of the Mind and Nervous System in the University of New York, &c.

"I have for some time made use of the Buffalo Lithia Water in cases of affections of the **NERVOUS SYSTEM,** complicated with **BRIGHT'S DISEASE OF THE KIDNEYS** or with a **GOUTY DIATHESIS.** The results have been eminently satisfactory. Lithia has for many years been a favorite remedy with me in like cases, but the **BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION OF THE LITHIA SALTS,** and is, moreover, better borne by the Stomach. I also often prescribe it in those cases of **CEREBRAL HYPERÆMIA** resulting from over-mental work—in which the condition called **NERVOUS DYSPEPSIA EXISTS**—and generally with marked benefit."

HUNTER McGUIRE, M.D., LL.D., Late Professor of Surgery, Medical College of Virginia, Richmond.

"**BUFFALO LITHIA WATER,** *Spring No. 2,* as an **ALKALINE DIURETIC,** *is invaluable.* In **URIC ACID GRAVEL,** *and, indeed,* in *diseases generally dependent* upon a **URIC ACID DIATHESIS,** *it is a remedy of extraordinary potency.* I have prescribed it in cases of **RHEUMATIC GOUT,** *which had resisted the ordinary remedies, with wonderful good results.* I have *used it also in my own case, being a great sufferer from this malady, and have derived more benefit from it than from any other remedy.*"

Dr. ROBERT BATTEY, of Georgia, SUGGESTER OF BATTEY'S OPERATION.

"I would state that I have been using the Buffalo Lithia Water, No. 2, in my practice for three years past, in cases of **CHRONIC INFLAMMATION** of the **BLADDER,** whether induced by **STONE,** by enlarged **PROSTATE** in the aged, or by **NEGLECTED GONORRHŒA, AND HAVE SECURED EXCELLENT RESULTS,** which encourages me to prescribe it for the future."

Dr. CYRUS EDSON, of New York,
Chief Inspector of Cutaneous Diseases in Health Department and President of the Board of Pharmacy.

"I have frequently made use of **BUFFALO LITHIA WATER,** Spring No. 2, in my practice, *with excellent results.* It is a potent remedy in correcting **RHEUMATIC DIATHESIS.** In a case of **URIC ACID GRAVEL,** in which I recently prescribed it, **ITS BENEFICIAL EFFECTS WERE APPARENT AFTER THE THIRD DOSE.** I have also prescribed it with great benefit in **BRIGHT'S DISEASE OF THE KIDNEYS.**"

Water in Cases of one dozen half-gallon Bottles, Five Dollars per Case, at the Springs.

Sodium Succinate, ... 2 " 5 "
Thalline Sulphate, ... 2, 3 " 5 "
Trinitrin (Nitro-Glycerin), 1-20, 1-25. 1-33, 1-50, 1-100, and 1-200 gr.
Terpin Hydrate, ... 2, 3 and 5 grs

ANTISEPTIC TABLETS.

7.7 Hydrarg. Chlor. Corros., 7.3 Ammonium Chloride.

More than six months since, we sent a circular to the drug trade, stating that we had discontinued the manufacture of the Antiseptic Tablets introduced by us several years since at the suggestion of Dr. Charles Meigs Wilson, of this city. We have, however, received so many letters from physicians urging us to resume the manufacture, insisting that the Tablets prepared by us dissolved more readily and were more satisfactory than any substitute they had been able to procure, that we feel we could not ignore such persistent demands from our medical friends who have found our tablets an absolute necessity. We have therefore concluded to again prepare them, in a building entirely separate from our main establishment, with appliances and admirably devised protection by means of improved respirators, that will completely overcome any harmful effects to those engaged in their manufacture.

Druggists and physicians will be glad to learn that the Tablets as now prepared are perfectly white and free from the coloring-matter that we formerly added. This was done to lessen the danger of their being taken, or used in mistake; to guard against any such possibility, each Tablet, as now made, has the word "POISON" stamped upon it.

JOHN WYETH & BROTHER,

CHEMISTS, PHILADELPHIA.

PHYSICIANS' LEDGER

Think how much time you have spent in this year over your accounts, and what a bother it has been to make out your bills!

Now one of the great merits of

The Model Ledger

is that it enables a physician to make out his bills with great ease. Besides this, it tells at a glance just how much he has earned in any quarter; how much he has received; and how much is still due him. These are all good things for a doctor to know.

Send Four Dollars and get one. Make check or Money Order payable to

BUFFALO LITHIA WATER

IN THE TREATMENT OF CHRONIC GASTRIC CATARRH

CLINICAL REPORTS.

CHRONIC GASTRIC CATARRH AND URIC ACID CALCULI.

A case stated by Dr. JNO. C. COLEMAN, of Scottsburg, Va., a retired Surgeon of the U. S. Navy.

"Mr. C. was for a number of years a sufferer from **CHRONIC GASTRIC CATARRH.** While his diet *was exclusively* **TEA** and **CRACKERS, BREAD** and **MILK,** *and other similar articles,* it was frequently thrown off in an undigested state soon after taking it, and at times he discharged from an empty stomach a strongly acid glairy mucus. A marked **URIC ACID DIATHESIS** supervened, consequent upon which he suffered for a period of some two years great **VESICAL IRRITATION** and possible **CYSTITIS,** attended by pain so intense and constantly present, as to require that he should be kept for the most part under the influence of opiates. After a persistent, but ineffectual exhibition of all remedies supposed to be indicated in the case, he was put for the latter affection upon the **BUFFALO LITHIA WATER,** Spring No. 2, with the happiest possible effect.

"In a few weeks, after commencing the use of it, the irritable condition of the *Bladder* was so far relieved that he was enabled to dispense entirely with the use of opiates. At the expiration of some eight weeks he had an attack of unusual severity, from which he was relieved by the discharge of a **CALCULUS,** followed at short intervals by the discharge of three others, which proved to be the termination of this trouble, as from that time there was entire subsidence of the painful symptoms described, and the *Bladder* resumed its natural state.

"While prescribed with special reference to the relief of the *Irritable Bladder,* the action of the water was not less surprisingly happy in the **GASTRIC AFFECTION,** with remarkable promptness correcting the highly acid condition of the **STOMACH,** restoring a healthy digestion and assimilation, and *tone* and *vigor* to the depressed *Nervous System.*

"In a few months he was able to eat, with perfect impunity, the coarsest articles of diet. He is now, after a lapse of several years, in robust health, having had no return of these painful maladies."

CHRONIC GASTRIC CATARRH.

Case of JOHN P. KEELING, Esq., stated by Dr. S. S. KEELING, Norfolk, Va., Member Medical Society of Virginia.

"Mr. John P. Keeling labored under **CHRONIC DYSPEPSIA,** and was always subject to attacks of *Spasmodic Gastralgia* immediately upon taking food into the stomach, which attacks were not at all amenable to treatment. Not unfrequently the stomach *rejected everything in the way of food and drink,* and he was of necessity confined to the lightest possible articles of diet, *meat and vegetables being entirely excluded.* He became so prostrated that it was with difficulty he could walk across his chamber floor, and had often to be lifted about. Such was the state of his **NERVOUS SYSTEM** *that great solicitude was felt as to his mental condition.*

"He visited Baltimore for medical aid, and was for many months under the treatment of some of the most eminent men of the profession in that city, but without beneficial result, and was finally advised that he had nothing to hope from remedies.

"Returning in an extremely critical condition to his home in the county of Princess Anne, he came under my professional care. Satisfied that medicine was unavailing in the case, I advised the **BUFFALO LITHIA WATER,** Spring No. 2. His stomach, however, was in a highly irritable condition, and I found it necessary to administer it in very small quantities; and it was at first given not exceeding an ounce at a dose, repeated at stated intervals. At the expiration of the third day the irritability of the stomach was decidedly less, and the quantity was then increased from day to day until the thirteenth day, when I found that the patient could take twelve ounces, which I regard as maximum dose at any time. Persisting in its use, on the twenty-eighth day he was free from pain, the stomach in a normal condition readily receiving both solids and liquids in moderate quantities, strength greatly increased, and nervous symptoms entirely relieved. At the expiration of the seventh week he was able to attend actively and regularly to his business on the farm. His recovery, which I regard as one of the most remarkable I ever knew of, I attribute entirely to the **BUFFALO LITHIA WATER."**

GASTRO-INTESTINAL CATARRH.

Case of Mrs. Dr. F. J. GREGORY, of Virginia, reported by F. J. GREGORY, M.D., Keysville, Va.

"For eighteen months my wife, aged forty-one years, was a sufferer from a **GASTRO-INTESTINAL CATARRH,** which resisted my best-directed efforts at relief. The taking of the smallest quantity of the most easily-digested food on the stomach would produce an attack of *nausea and vomiting, the severity of which is seldom witnessed,* and when the stomach was free of food she would have attacks of *Gastralgia of the most excruciating nature.* She also suffered from habitual constipation, and at times with hemorrhages from the bowels. I pursued the usual line of treatment, such as simple bitters, Dilute Hydrocyanic Acid, Bismuth, etc., and called to my help two of the most skilled physicians in Southside Virginia, who supplemented my treatment with some of the newer drugs, such as **EFFERVESCING BICARB. POTASS. LACTOPEPTINE, CARLSBAD MINERAL SALTS,** etc., but with no benefit, and so her condition went on from bad to worse *until death seemed almost imminent from inanition.* I then put her on a milk diet with a glass of **BUFFALO LITHIA WATER,** Spring No. 2, every hour or so during the day, and *after the use of the first bottle improvement was marked, and before a case of it was used I regarded her cure as complete.* It has been nearly two years since, and there has been only one slight recurrence, which was a few days since, and it readily disappeared on the use of the water for a few days."

Water in cases of one dozen half-gallon bottles, $5 per case, at the Springs.

THOMAS F. GOODE, Proprietor,

BUFFALO LITHIA SPRINGS, VIRGINIA.

THE NEW HYPNOTIC
SULFONAL-BAYER.

SULFONAL was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

SULFONAL (Diæthylsulfondimethylmethan) is in the form of colorless prisms, odorless, and tasteless, melting at 125.5° C. (258° F.) and has the composition $(C H_3)_2{=}C{=}(C_2 H_5 SO_2)_2$. It is slightly soluble in cold water, but easily soluble in hot water or alcohol.

SULFONAL was first examined as to its physiological and pathological effects by Prof. A. Kast, of Freiburg University and its hypnotic action was discovered and studied by him.

Since then SULFONAL has been the subject of numerous trials and experiments by many eminent and experienced physicians. Their testimony is unanimously favorable, and the conclusions reached by them are as follows:

SULFONAL is a prompt and reliable hypnotic, which in proper doses, produces quiet, natural sleep, lasting a number of hours.

SULFONAL has no unfavorable effects on the heart and the circulation, nor on the temperature, the pulse, or the respiration.

SULFONAL produces no disagreeable secondary symptoms; the patients with very few exceptions awake from their sleep feeling strong and greatly refreshed.

SULFONAL does not interfere with the process of digestion.

SULFONAL is a hypnotic, and not a narcotic; it acts by giving rest to the cells of the cerebral cortex, thereby causing sleep.

SULFONAL does not create an unconquerable desire for its repeated use; there is no danger of a SULFONAL-habit Neither is it necessary to increase the dose after long-continued use.

SULFONAL is best administered at supper-time, dissolved in hot liquids, *e. g.*, a bowl of soup or broth, a cup of milk, tea, coffee, cocoa, etc.

These points will be found to be fully exhibited in the series of contributions contained in our pamphlet, which will be mailed on application.

SULFONAL-BAYER is supplied by us in half-ounce and one-ounce vials.

We prepare 5-grain and 15-grain Tablets of Sulfonal-Bayer. The tablet form is admirably adapted to the purpose of administering this drug, as when they are placed in the liquids, they disintegrate and are thus received into the system.

We also put up Sulfonal-Bayer in the form of our Soluble Pills, containing five grains each.

THE NEW ANTIPYRETIC
PHENACETINE-BAYER.

Phenacetine-Bayer (Para-Acetphenetidine) is a white, glossy, crystalline powder, perfectly tasteless, melting at 135° C.=307° F and has the composition $C_6 H_4 <^{O.C_2H_5}_{NH(CO-CH_3)}$.

It is slightly soluble in water, a little more soluble in glycerine, but most freely in alcohol.

Phenacetine-Bayer was first prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, and is of absolute purity and uniform quality.

Summarizing the superiority of Phenacetine-Bayer over other antipyretics and antineuralgics, the following conclusions are formed:

1. ***Phenacetine-Bayer is an efficacious antipyretic.***
2. ***It does not develop any disagreeable or noxious after-effects.***
3. ***The dose required is half that of Antipyrine.***
4. ***It is perfectly tasteless.***
5. ***On account of its innocuousness and tastelessness, it is a valuable antipyretic both in adults and in children.***
6. ***Phenacetine-Bayer is an important antineuralgic; its effect is more energetic than that of Antipyrine and does not cause lassitude or any other disagreeable symptoms.***

Our pamphlet on Phenacetine-Bayer, containing the valuable testimony of eminent physicians will be mailed on application.

We offer Phenacetine-Bayer in one-ounce vials, or in the form of our Soluble Pills of the strength of two and four grains to each pill.

Made as Soft and Digestible as that of
Woman's Milk.

"From experiments which I have recently made — and my thanks are due to Prof. Salisbury of the Woman's Medical College, for assistance — it seems that the claim which is made by the advocates of the MELLIN'S FOOD is true, and that the addition of this food to cow's milk does cause it to break up in very small, flaky curds."— *Dr. Chas. Warrington Earle, Professor of Diseases of Children, Woman's Medical College, Professor of Obstetrics, College Physicians and Surgeons, Chicago, in his paper on Infant Feeding, before the American Medical Association, May, 1888.*

Any physician having a case in which he desires to test MELLIN'S FOOD can obtain a sample sufficient for trial, free of all expense, by application.

Doliber-Goodale Co., Boston, Mass.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

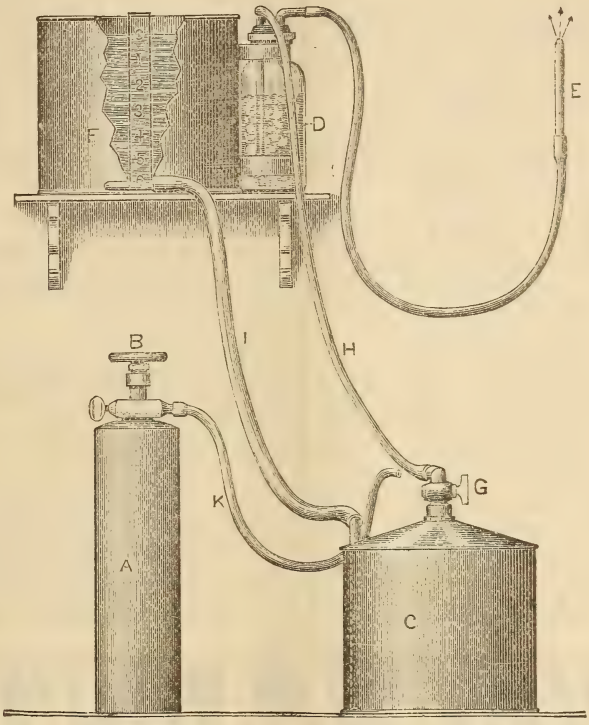
PURE OXYGEN

AND

APPARATUS FOR ITS THERAPEUTIC ADMINISTRATION



At the solicitation of a number of medical practitioners interested in oxygen treatment, we have devised apparatus for the therapeutic administration of this gas both by inhalation and by enema. We present an illustration of the latter. It is provided with a gauge by which the quantity of gas administered can be readily ascertained. We believe the apparatus we offer will be found to be the most convenient and economical device for the purpose on the market. We are prepared to supply Pure Oxygen Gas, or a mixture of Oxygen and Nitrous Oxide in definite proportions respectively of 20 per cent. and 40 per cent. of Nitrous Oxide, in cylinders of 40 or 100 gallons each. Full directions sent with each apparatus.

PRICES.

ENEMA APPARATUS	$12.00
INHALING APPARATUS	5.00
FORTY GALLON CYLINDER	6.00
FORTY GALLON CYLINDER FILLED	8.00
ONE HUNDRED GALLON CYLINDER	15.00
ONE HUNDRED GALLON CYLINDER FILLED	20.00

The Gas whether pure or mixed is supplied at the uniform price of 5 cents per gallon. The cost of the cylinders will be refunded on their return empty, with the valves in good condition.

THE S. S. WHITE DENTAL MFG. CO.,

PHILADELPHIA, NEW YORK, BOSTON, CHICAGO, BROOKLYN.

RABUTEAU'S DRAGEES OF IRON

Laureate of the Institute of France.—Prize in Therapeutics.

The studies made by the Physicians of the Hospitals have demonstrated that the **Genuine Dragees of Iron of Rabuteau** are superior to all other preparations of Iron in cases of *Chlorosis, Anæmia, Leucorrhœa, Debility, Exhaustion, Convalescence, Weakness of Children*, and the maladies caused by the Impoverishment and Alteration of the blood after periods of fatigue, watching, and excesses of any kind.

TAKE 4 TO 6 DRAGEES DAILY.

Rabuteau's Elixir of Iron is recommended to those persons who may be unable to swallow the Dragees. Dose —*A small wineglassful with meals.*

Rabuteau's Syrup of Iron is specially designed for children. Chalybeate medication, by means of **Rabuteau's Iron**, is the most economical and the most rational known to therapeutics.

No constipation, no diarrhœa, complete assimilation.

Take only the GENUINE IRON OF RABUTEAU of

CLIN & CO., Paris.

SOLUTION OF

THE SALICYLATE OF SODA OF DOCTOR CLIN.

Laureate of the Paris Faculty of Medicine (MONTYON PRIZE).

Dr. Clin's Solution, always identical in its composition, and of an agreeable taste, permits the easy administration of *pure Salicylate of Soda*, and the variation of the dose in accordance with the indications presented.

"The *Salicylate of Soda* used by **Clin** is of perfect purity, "and is prepared with the greatest care; it is a medicament "in which we may have every confidence."

—*Paris Society of Medicine, Meeting of Feb. 8th, 1879.*

Clin's Solution, very exactly mixed, contains: 2 grammes of *Salicylate of Soda* per tablespoonful, 50 centigrammes of *Salicylate of Soda* per teaspoonful.

Paris—CLIN & CO.—Paris

AND BY ALL DRUGGISTS.

CAPSULES MATHEY-CAYLUS

WITH THIN ENVELOPE OF GLUTEN.

CONTAINING COPAIBA AND ESSENCE OF SANTAL; COPAIBA, CUBEBS, AND THE ESSENCE OF SANTAL; COPAIBA, IRON, AND THE ESSENCE OF SANTAL.

"**The Mathey-Caylus Capsules,** of the *Essence of "Santal*, associated with the Balsams, possess an incontesta- "ble efficaciousness, and are employed with the greatest "success for the rapid cure of old or recent *Discharges*, "*Gonorrhœa, Blenorrhœa, Leucorrhœa, Cystitis of the Neck*, "*Urethritis, Catarrh*, and other *diseases of the bladder*, together "with all affections of the *Urinary Passages*."

"Thanks to their thin envelope of *Gluten*, which is essen- "tially assimilable, the *Mathey-Caylus Capsules* are digested "by the most delicate persons, and never weary the stomach."

—*Gazette des Hopitaux de Paris.*

NEURALGIAS

PILLS OF DR. MOUSSETTE.

The **Moussette Pills** of aconitine and quinium, calm or cure *Gastralgia, Hemicrania, Headache, Sciatica*, and the most obstinate Neuralgias.

"The sedative action exerted by the **Moussette Pills** "upon the apparatus of the sanguineous circulation by the "intermediation of the vaso-motor nerves, indicates their "use in *neuralgias of the trigemini nerves*, (fifth pair), *con-* "*gestive neuralgias*, and *painful and inflammatory Rheumatismal* "*affections*."

"Aconitine produces marvelous effects in the treatment "of *facial neuralgias* when they are not symptomatic of "intracranial tumor."—*Society of Biology of Paris, Meeting* "*of the 28th February, 1880.*

DOSE—Take 3 to 6 pills during the twenty-four hours.

ACCEPT ONLY THE GENUINE MOUSSETTE PILLS OF

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

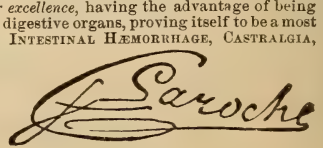
FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.



E. FOUGERA & CO., New York,

Sole Agents for the United States for the above Preparations.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 1872, 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonary Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE., Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlets or other information, address

E. FOUGERA & CO., 30 North William St., New York,

Sole Agents for the above Preparations.

CELERINA

NERVE TONIC, STIMULANT AND ANTISPASMODIC.

FORMULA.—Every Fluid Drachm represents FIVE grains EACH—Celery, Coca, Kola, Viburnum and Aromatics.

INDICATIONS.—Loss of Nerve-Power (so usual with Lawyers, Preachers, Writers and Business Men), Impotency, Spermatorrhea, Nervous Headache, Neuralgia, Paralysis, Hysteria, Opium Habit, Inebriety, Dyspepsia, and ALL LANGUID conditions of the System.

Indispensable to restore a patient after alcoholic excess.

DOSE.—One or two Teaspoonfuls three or more times a day, as directed by the Physician.

LIQUID IRON-RIO

Palatable and easily assimilated. Does not produce Nausea, nor irritate the Stomach. Does not Cause Headache, nor Constipate. Does not Stain the Teeth. It is so Acceptable to the Stomach that its Use is Admissible when all other forms of Iron would be rejected. Being so Readily Assimilable, it only requires a small Dose.

Each Fluid Drachm contains ONE GRAIN of Iron in a Pleasant and Digestible Form.

DOSE.—One or more Teaspoonfuls as indicated, during or after meals.

S. H. KENNEDY'S

CONCENTRATED EXTRACT OF

PINUS CANADENSIS

DARK. A NON-ALCOHOLIC LIQUID. WHITE.

A MOST VALUABLE NON-IRRITATING MUCOUS ASTRINGENT.

INDICATIONS.—Albuminuria, Diarrhea, Dysentery, Night-Sweats, Hemorrhages, Profuse Expectoration, Catarrh, Sore Throat, Leucorrhea, and other Vaginal Diseases, Piles, Sores, Ulcers, Burns, Scalds, Gonorrhea, Gleet, Etc.

When Used as an Injection, to Avoid Staining of Linen, the WHITE Pinus should be used.

RECOMMENDED BY PROMINENT EUROPEAN AND AMERICAN PHYSICIANS.

Established 1866. **Philadelphia.**

An Important Communication
TO PHYSICIANS.

Thirteen years have now elapsed since the introduction of SCOTT'S EMULSION of PURE NORWEGIAN COD LIVER OIL with HYPOPHOSPHITES of LIME and SODA, since which time its growth and development have been very large, not only in this country but in South America, Great Britain and a large part of Continental Europe, and it has, in a very large degree, supplanted the Plain Cod Liver Oil. Its success is largely due to the happy combination of all its components, making a perfect chemical union, that will not separate for years, which we believe is not true of any other Cod Liver Oil preparation.

The innumerable reports from Physicians, of the brilliant results obtained justifies the statement that in almost every case where Cod Liver Oil is indicated, Scott's Emulsion is infinitely superior.

Physicians who have never tried this Emulsion, or who have been induced to try something else in its stead, will do us the favor to send for sample, and we know they will always use it in preference to plain Cod Liver Oil or any other preparation.

We also call your attention to the following preparations:

CHERRY-MALT PHOSPHITES.

A combination of the tonic principles of Prunus Virginiana, Malted Barley, Hypophosphites of Lime and Soda, and Fruit Juices. An elegant and efficient brain and nerve tonic.

BUCKTHORN CORDIAL (Rhamnus Frangula.)

Prepared from carefully selected German Buckthorn Bark, Juglans Bark, and Aromatics. The undoubted remedy for Habitual Constipation.

Be sure and send for samples of the above—delivered free.

SCOTT & BOWNE, 132 South Fifth Ave., New York

McARTHUR'S SYRUP.

(SYR: HYPOPHOS: COMP: C. P. McARTHUR.)

Its use is indicated in Consumption and Tuberculosis, Diseases of the Chest, Chronic Cough, Throat Affections, General Debility, Brain Exhaustion, Impotence and Loss of Memory.

The point of primary importance in the use of the Hypophosphites is their *chemical* purity, but unfortunately they are too often adulterated.

So little seems to be generally known, even among the medical profession, with regard to the chemistry of the Hypophosphites, and the absolute necessity of CHEMICAL purity, that we call attention to this point.

One of the first effects produced by the use of our CHEMICALLY PURE Hypophosphites is a general increase of nervous energy, with a feeling of ease and comfort.

The second effect is an increase of appetite; digestion is improved, and the bowels become regular in their action, the quantity and color of the blood is increased, respiration is controlled, a better expansion of the chest is observed, cough improves, easy expectoration is produced, night perspiration diminishes, the face becomes fuller, the lips red, the nails and hair grow, and in children the teeth, showing the importance of the Hypophosphites on the organ of nutrition.

☞ Physicians when prescribing will please write thus:

℞ SYR: HYPOPHOS: COMP: McARTHUR. ONE BOTTLE.

As it is made *only for physicians* there are no printed wrappers or advertisements about the bottle.

Our pamphlet on the **CURABILITY AND TREATMENT OF CONSUMPTION,** sent free to physicians upon application.

We will send one bottle of McArthur's Syrup to any physician, without charge, who will pay the express charges on the same.

THERE IS A PEPSIN

WHICH IS UNIFORMLY ACTIVE, PERMANENT, AND RELIABLE,

IT IS "FAIRCHILD'S."

This Pepsin will not spoil, will not become soft and sticky in the vial, even if left long uncorked.

Fairchild's Pepsin will not "gum up" if dispensed in powders, plain, or with the drugs usually combined with pepsin.

Fairchild's is not a partial peptone, and has none of the well-known characteristics of peptone.

Fairchild's is the pioneer pepsin, it showed the way. It "got there" early.

Its activity has never been exaggerated.

All this time, whilst other manufacturers were still offering the high-dilution saccharated and amylated article, Fairchild's Pepsin was steadily making its way on its merit. Now, no one ventures to ask a hearing for these *placebo-pepsins.*

When physicians now prescribe "pepsin" they mean pepsin—not milk sugar, and pepsin.

All these years, Fairchild's Pepsin was always and everywhere found to do just what was claimed for it—in spite of the attitude, genuine or assumed, which held that all "claims" about pepsin must be taken with a liberal discount.

Every *bona fide* test demonstrated its reliability.

We have never found it necessary to explain or excuse any deficiency or inaction as due to "deteriorated" specimens.

Fairchild's will not disappoint the prescriber under any condition proper for pepsin.

With Such a Record Fairchild's Pepsin is a good one to stand by.

READ the Suggestions to contributors and correspondents on First Editorial Page.

For more than four years the Perfection Douche has been subjected to the severest practical tests, by experienced gynaecologist in every part of this country, no objection, in a single instance, having been made to the principles upon which it is constructed.

It provides ample and comfortable support, with a slight elevation of either the shoulders or hips, furnishes means for the prolonged application of a sufficiently large amount of hot water, and completely conveys away all the drip without risk of wetting the clothing. No other apparatus for applying hot water in the treatment of uterine and pelvic diseases combines as many desirable and practical qualities. COMFORT, CONVENIENCE, DURABILITY, AND THOROUGHNESS OF APPLICATION are its main points of excellence.

Descriptive circulars, prices, and testimonials are furnished on application. These afford satisfactory evidence of unqualified endorsement of its superior advantages, and show the high appreciation in which the instrument is held by those who have repeatedly recommended and tested its work.

Applications for the Douche or for circulars or testimonials may be made to agents, or to "THE PERFECTION DOUCHE," Box 7, ALBANY, N. Y.

University of Pennsylvania
MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,
36th and Woodland Ave., Phila.

DETROIT COLLEGE OF MEDICINE.
SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

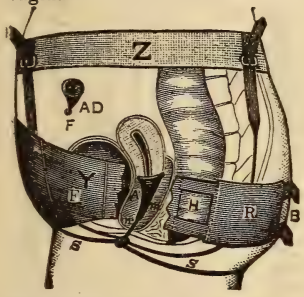
STAUFER'S

UTERINE SUPPORTER

HARD RUBBER. SPRING STEM.

This supporter, as now made, is the result of seventeen years' experience in manufacturing instruments for the treatment of displacements of the womb, aided by the suggestions of a large number of practitioners who have used these well-known supporters in the past.

The construction of the instrument shown in the cut is such that the cup inclines forward, and this inclination, together with the curve in the stem adapts it to the axis of the uterus and vagina.



There is a Coil-spring in the tube at *m*, which prevents shock to the womb when the patient sits down.

The instrument is held in position by means of a belt (Z or Y) and elastic cords (S S). One form of belt (Z) surrounds the waist; another (Y) is made like an abdominal supporter. The belts are made of 3-ply, fine cotton material, with elastic hip-straps, and buckle at the back.

Self-Sustaining Supporter.—The supporter may also be used without a belt, when no great bodily exertion calls for the latter. A little stem (F) is screwed on the cup (A), instead of the longer stem (*n*), as shown in the figure A D, and the instrument becomes self-sustaining.

The cup is made in sizes ranging from 1¼ inches to 2¼ inches in diameter, the difference from one size to another being ⅛ inch. The size most frequently used is 1¾ inches across the cup.

SELECTION In ordering, give exact measure around the hips, just below crest of ilium, and the width of cup on top, as nearly as this can be estimated.

EXCHANGE Dr. Staufer will exchange one size of the supporter for another, if desired. PROVIDED the request is made within a reasonable time, and when the *three rubber parts* are returned in good condition.

THE BELTS ARE NOT EXCHANGED.

Because they are apt to show the effect of use, and there is no trouble about getting a good fit, if the correct measure is sent.

PRICE

The instrument complete, with belt Z, costs	$4.00
" " " " " Y, "	5.00

WHEN OUR

MODEL LEDGER

lies open it looks like this, and what is shown here measures 18 x 11½ inches.

EASY BOOK-KEEPING. EASY MAKING OUT BILLS.

Quarto. Size of Page 9 x 11½ inches.

Handsomely ruled in red and blue, and printed in black, on fine ledger paper. Bound in black cloth, with leather back and corners. OPENS OUT FLAT. 300 pages and index. Space for over 2000 accounts. A copy will be sent to any address on receipt of price, and, if it is not approved when seen, the money will be refunded upon return of the book and cost of transportation one way.

PRICE - $4.00.

Address, MEDICAL AND SURGICAL REPORTER.

P. O. Box 843, Philadelphia.

PHYSICIANS' LEDGER

Think how much time you have spent in this year over your accounts, and what a bother it has been to make out your bills!

Now one of the great merits of

The Model Ledger

is that it enables a physician to make out his bills with great ease. Beside this, it tells at a glance just how much he has earned in any quarter; how much he has received; and how much is still due him. These are all good things for a doctor to know.

Send Four Dollars and get one. Make check or Money Order payable to

HYDROLEINE

(HYDRATED OIL)

FOR CONSUMPTION and WASTING DISEASES,

Produces Immediate Increase in Flesh and Weight.

FORMULA.

Each Dose of Two Teaspoonfuls equal to 120 Drops, contains:

Pure Cod Liver Oil...80 m. (drops)	Soda.....1.3 Grains.
Distilled Water.....35 "	Salicylic Acid.....1.4 "
Soluble Pancreatin.. 5 Grains.	Hyocholic Acid.....1.20 "

DOSE.—Two teaspoonfuls alone, or with twice the quantity of water to be taken thrice daily after meals.

HYDROLEINE (Hydrated Oil) is not a simple alkaline emulsion of oleum morrhua, but a hydro-pancreated preparation containing acids and a modicum of soda. Pancreatin is the digestive principle of fatty foods, and in the soluble form here used completely saponifies the oleaginous material so necessary to the reparative process in all wasting diseases.

Each bottle in nutritive value exceeds ten times the same bulk of cod liver oil. It is economical in use and certain in results.

The principles upon which this discovery is based have been described in a treatise on "The Digestion and Assimilation of Fats in the Human Body," by H. C. BARTLETT, Ph.D., F. C. S., *and the experiments which were made, together with cases illustrating the effect of Hydrated Oil in practice, are concisely stated in a Treatise on "Consumption and Wasting Diseases," by* G. OVEREND DREWRY, M.D. ***Copies of these works sent free on application.***

SOLD AT ALL DRUG STORES, AT $1.00 PER BOTTLE.

C. N. CRITTENTON,

Sole Agent for the United States. **115 FULTON ST., NEW YORK.**

A sample of Hydroleine will be sent free upon application, to any physician (inclosing business card) in the United States.

FELLOWS'

HYPO-PHOS-PHITES

(SYR: HYPOPHOS: COMP: FELLOWS)

Contains **The essential elements** to the Animal Organization—Potash and Lime.

The **Oxydizing Agents**—Iron and Manganese;

The **Tonics**—Quinine and Strychnine,

And the **Vitalizing Constituent**—Phosphorus,

Combined in the form of a Syrup, with *slight alkaline reaction.*

It Differs in Effect from all others, being pleasant to taste, acceptable to the stomach, and harmless under prolonged use.

It has Sustained a High Reputation in America and England for efficiency in the treatment of Pulmonary Tuberculosis, Chronic Bronchitis, and other affections of the respiratory organs, and is employed also in various nervous and debilitating diseases with success.

Its Curative Properties are largely attributable to Stimulant, Tonic, and Nutritive qualities, whereby the various organic functions are recruited.

In Cases where innervating constitutional treatment is applied, and tonic treatment is desirable, this preparation will be found to act with safety and satisfaction.

Its Action is Prompt; stimulating the appetite and the digestion, it promotes assimilation, and enters directly into the circulation with the food products.

The Prescribed Dose produces a feeling of buoyancy, removing depression or melancholy, and hence is of great value in the treatment of MENTAL AND NERVOUS AFFECTIONS.

From its exerting a double tonic effect and influencing a healthy flow of the secretions, its use is indicated in a wide range of diseases.

Prepared by JAMES I. FELLOWS, Chemist,

48 VESEY STREET, NEW YORK.

Circulars sent to Physicians on Application.

---o---

Dear Doctor:

I beg your co-operation in endeavoring to get all the subscribers to the MEDICAL AND SURGICAL REPORTER to cordially accept a condition usual with first-class periodicals, that is, that subscriptions shall be paid in advance. There are still some of our subscribers who have accounts unsettled for the year 1888, and they are urged to pay this amount and the price for the year 1889 as soon as possible.

The evidences of approval of the REPORTER by medical men are multiplying. The subscription list is growing larger, and it is hoped that all who are now subscribers will long continue their patronage, and that they will heartily support the publisher in endeavoring to maintain those principles of business which experience shows to be best for all, not only for the publishers but for also the subscribers.

SO SEND WHAT YOU OWE, SOON.

Make all checks or money-orders payable to

CHARLES W. DULLES.

LEGS and ARMS with RUBBER FEET and HANDS

(MARKS' PATENTS.)

Indorsed by the United States Government, the Industrial Exhibition Commissioners of New York, Philadelphia, Atlanta, New Orleans, etc., the eminent surgeons in the country, the press, and over 9,000 men, women, and children who wear them, residing in all parts of the world.

The Rubber Foot and Hand possess the most natural appearance, the greatest durability and comfort of all artificial limbs. Vast numbers of mutilated men and women are, by the use of rubber feet and hands, enabled to mingle with the rest of the world without betraying their loss or experience great inconvenience. Farmers, mechanics. professionals, and even athletes, who have lost one or more of their limbs, are enabled to resume their vocations by the use of these remarkable inventions.

MR. A. A. MARKS: ITHACA, TOMPKINS CO., N.Y., Jan. 15, 1888.

DEAR SIR: Rubber feet are the wonders of the world. I have challenged every maker in the world to produce a man that has a pair of artificial feet to walk with me. I can walk a mile in thirteen minutes, and not hurry myself any. I do not take a back seat for any unprofessional with two good natural feet, in a one mile walk. I have the pleasure of announcing that my record in walking professionally is unequaled in the world by any one with artificial legs. THOMAS CLEARY.

By a copyright formula, furnished by us on request, applicants can supply us with all the data necessary to secure fit and satisfactory results, while they remain at home. One-half the legs and arms furnished by us are made from measurements and profiles, without our seeing the wearer. This new method is a great convenience for those living at a distance. Fit always guaranteed.

A treatise of 400 pages, and nearly 200 illustrations, and nearly a thousand endorsements and testimonals, sent to those needing artificial legs or arms, who will give a description of their case. The same will be sent to physicians and surgeons free of charge. Address,

A. A. MARKS, 701 Broadway, New York City.

IF

You have never prescribed Lactated Food, why not do so NOW? A scientific preparation, its formula recommends it to every physician.

Anyway, let us send you our complimentary portfolio of baby pictures—they are beauties. Sample of Lactated Food mailed to any physician unacquainted with its merits.

WELLS & RICHARDSON CO., Proprietors

BURLINGTON, VT.

THE NEW HYPNOTIC
SULFONAL-BAYER.

SULFONAL was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

SULFONAL (Diæthylsulfondimethylmethan) is in the form of colorless prisms, odorless, and tasteless, melting at 125.5° C. (258° F.) and has the composition $(C H_3)_2=C=(C_2 H_5 SO_2)_2$. It is slightly soluble in cold water, but easily soluble in hot water or alcohol.

SULFONAL was first examined as to its physiological and pathological effects by Prof. A. Kast, of Freiburg University and its hypnotic action was discovered and studied by him.

Since then SULFONAL has been the subject of numerous trials and experiments by many eminent and experienced physicians. Their testimony is unanimously favorable, and the conclusions reached by them are as follows:

SULFONAL is a prompt and reliable hypnotic, which in proper doses, produces quiet, natural sleep, lasting a number of hours.

SULFONAL has no unfavorable effects on the heart and the circulation, nor on the temperature, the pulse, or the respiration.

SULFONAL produces no disagreeable secondary symptoms; the patients with very few exceptions awake from their sleep feeling strong and greatly refreshed.

SULFONAL does not interfere with the process of digestion.

SULFONAL is a hypnotic, and not a narcotic; it acts by giving rest to the cells of the cerebral cortex, thereby causing sleep.

SULFONAL does not create an unconquerable desire for its repeated use; there is no danger of a SULFONAL-habit Neither is it necessary to increase the dose after long-continued use.

SULFONAL is best administered at supper-time, dissolved in hot liquids, *e. g.*, a bowl of soup or broth, a cup of milk, tea, coffee, cocoa, etc.

These points will be found to be fully exhibited in the series of contributions contained in our pamphlet, which will be mailed on application.

SULFONAL-BAYER is supplied by us in half-ounce and one-ounce vials.

We prepare 5-grain and 15-grain Tablets of Sulfonal-Bayer. The tablet form is admirably adapted to the purpose of administering this drug, as when they are placed in the liquids, they disintegrate and are thus received into the system.

We also put up Sulfonal-Bayer in the form of our Soluble Pills, containing five grains each.

THE NEW ANTIPYRETIC
PHENACETINE-BAYER.

Phenacetine-Bayer (Para-Acetphenetidine) is a white, glossy, crystalline powder, perfectly tasteless, melting at 135° C.=307° F and has the composition $C_6 H_4 \begin{matrix} O.C_2H_5 \\ NH\,(CO-CH_3) \end{matrix}$.

It is slightly soluble in water, a little more soluble in glycerine, but most freely in alcohol.

Phenacetine-Bayer was first prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, and is of absolute purity and uniform quality.

Summarizing the superiority of Phenacetine-Bayer over other antipyretics and antineuralgics, the following conclusions are formed:

1. ***Phenacetine-Bayer is an efficacious antipyretic.***
2. ***It does not develop any disagreeable or noxious after-effects.***
3. ***The dose required is half that of Antipyrine.***
4. ***It is perfectly tasteless.***
5. ***On account of its innocuousness and tastelessness, it is a valuable antipyretic both in adults and in children.***
6. ***Phenacetine-Bayer is an important antineuralgic; its effect is more energetic than that of Antipyrine and does not cause lassitude or any other disagreeble symptoms.***

Our pamphlet on Phenacetine-Bayer, containing the valuable testimony of eminent physicians will be mailed on application.

We offer Phenacetine-Bayer in one-ounce vials, or in the form of our Soluble Pills of the strength of two and four grains to each pill.

W. H. SCHIEFFELIN & CO.,

170 & 172 WILLIAMS STREET, NEW YORK,

SOLE LICENSEES AND SOLE AGENTS FOR THE UNITED STATES.

SUCCUS ALTERANS

(McDADE.)

SUCCUS ALTERANS is a purely vegetable compound of the preserved juices of Stillingia Sylvatica Lappa Minor, Phytolacca Decandra, Smilax Sarsaparilla, and Xanthoxylum Carolinianum, as collected by Dr. Geo. W. McDade, exclusively for Eli Lilly & Co., and endorsed by Dr. J. Marion Sims.

SUCCUS ALTERANS continues to gain favor from its remarkable Alterative and Tonic properties, *eliminating specific poison from the blood* and *increasing the proportion of red corpuscles in anæmic patients* to a wonderful degree; is endorsed by the medical profession, and in use by many hospitals of note.

SUCCUS ALTERANS in venereal and cutaneous diseases is fast supplanting Mercury, the Iodides, and Arsenic; and is a certain remedy for Mercurialization, Iodism, and the dreadful effects often following the use of Arsenic in skin diseases.

SUCCUS ALTERANS is also strongly recommended for its Tonic and Alterative effects in myriad forms of scrofulous disease, and in all cases where anæmia is a factor. Such patients rapidly develop a good appetite, sleep soundly, and gain flesh rapidly. Many cases are on record where patients increased ten to twenty-five pounds in weight in a few weeks.

SUCCUS ALTERANS is giving satisfactory results in treatment of *Chronic Rheumatism*, and can be used with confidence.

SUCCUS ALTERANS may be given for any length of time, without injury to the patient.

SUCCUS ALTERANS is put up in pint round amber bottles, and *never in bulk.*

PHYSICIANS who have not received Dr. McDade's latest publication, the Monographia Syphilitica, should send their address, mentioning this journal, and we will mail a copy. It contains a paper, illustrated with colored plates, by Dr. D. H. Goodwillie, of New York, on the "Sequelæ of Syphilis," reports of cases in practice, and many other valuable papers.

ELIXIR PURGANS.

Elixir Purgans (Lilly) reliably stimulates the dormant liver without undue irritation, and has gentle yet positive effect upon the alimentary tract. In Habitual Constipation, so common in Women and Children, it will be found particularly useful. Its endorsement at Bellevue and many other prominent hospitals East and West, as well as its employment in general practice by the most eminent medical men, confirms the experience of years in its use.

Each Teaspoonful Represents	
Rhamnus Purshiana, -	10 grs.
Euonymus Atropur., - -	8 grs.
Cassia Acutifolia (Purif.)	10 grs.
Iris Versicolor, - - -	4 grs.
Hyoscyamus Niger, -	2 grs.
Aromatics, etc.	

IN PRESCRIBING, PLEASE BE CAREFUL TO WRITE

ELIXIR PURGANS (LILLY),

THAT OTHER PREPARATIONS MAY NOT BE SUBSTITUTED.

HIGHLY RECOMMENDED.

We take pleasure in endorsing the Elixir Purgans (Lilly) as prepared from the above formula, for in it we find a near approach to positive *perfection* in the form of a *Liquid Cathartic*, and, from our experience with the preparation, can highly recommend it to the profession.

JAMES R. HEALY, M.D., *Sup't Infants' and Children's Hospital, Randall's Island, N. Y.*

NEURALGIAS

PILLS OF DR. MOUSSETTE.

The **Moussette Pills** of aconitine and quinium, calm or cure *Gastralgia, Hemicrania, Headache, Sciatica*, and the most obstinate Neuralgias.

"The sedative action exerted by the **Moussette Pills** "upon the apparatus of the sanguineous circulation by the "intermediation of the vaso-motor nerves, indicates their "use in *neuralgias of the trigemini nerves*, (fifth pair), *con-* "*gestive neuralgias*, and *painful and inflammatory Rheumatismal* "*affections.*"

"Aconitine produces marvelous effects in the treatment "of *facial neuralgias* when they are not symptomatic of "intracranial tumor."—*Society of Biology of Paris, Meeting* "*of the 28th February, 1880.*

DOSE—Take 3 to 6 pills during the twenty-four hours.

ACCEPT ONLY THE GENUINE MOUSSETTE PILLS OF

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.

E. FOUGERA & CO., New York,

Sole Agents for the United States for the above Preparations.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 1872, 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonary Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE., Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

THIRD EDITION.

ACCIDENTS AND EMERGENCIES

By CHARLES W. DULLES, M.D.

"This is the third edition, with revisions and enlargements, of an excellent manual, the practical qualities of which have been proved many times. It is a work that ought to be in every home, and every home that has a copy kept where it can be consulted at short notice is likely to find it worth many times its small cost."—*Philadelphia Evening Telegraph*, May 5, 1888.

"The illustrations are good and sufficiently numerous. The language is simple, being entirely devoid of technicalities, and the methods of treatment recommended are trustworthy and reliable. The manual is one of the best of this class of books and should be in the library of every householder, ready for reference at a moment's notice."—*Science*, May 18, 1888.

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

Planten's CAPSULES.

Known as reliable over FIFTY years for "General Excellence in Manufacture."

H. PLANTEN & SON, 224 William St., New York

Established 1836.

SOFT and HARD **CAPSULES** Filled of All Kinds.

Sizes: 3, 5, 10, and 15 Min., and 1, 2½, 5, 10, and 15 Gram.

NEW KINDS: SANDALWOOD, OIL OF WINTERGREEN, APIOL, ETC.

Improved. Empty, 8 Sizes.

Capacity in Grains, 12, 10, 5, 4, 2, 1, ½, ¼.

For taking medicines free of taste, smell, injury to the teeth mouth, or throat. Trial box, by mail, 25 cents.

RECTAL, 3 sizes. VAGINAL, 6 sizes. HORSE, 6 sizes
For LIQUIDS, 3 sizes.

CAPSULES FOR MECHANICAL PURPOSES.

New Articles, and Capsuling Private Formulæ a Specialty

SOLD BY ALL DRUGGISTS. SAMPLES FREE.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,
36th and Woodland Ave., Phila.

ALETRIS CORDIAL

UTERINE TONIC AND RESTORATIVE.

Prepared from the Aletris Farinosa or True Unicorn and Aromatics.

INDICATIONS.

Amenorrhea, Dysmenorrhea, Leucorrhea, Prolapsus Uteri, Sterility, to Prevent Miscarriage, Etc.

DOSE:—ONE TEASPOONFUL THREE OR FOUR TIMES A DAY.

UNRIVALED AS A UTERINE TONIC IN IRREGULAR, PAINFUL, SUPPRESSED AND EXCESSIVE MENSTRUATION.

It Restores Normal Action to the Uterus, and Imparts Vigor to the Entire Uterine System.

☞Where women have miscarried during previous pregnancies, or in any case where miscarriage is feared, the ALETRIS CORDIAL is indicated, and should be continuously administered during entire gestation.

CHAS. CLAY, M. R. C. S., Manor House, Dewsbury, England, says:—I find Aletris Cordial (Rio) is of great service in threatened miscarriage.

FRANCIS E. CANE, L. R. C. S., &c., Leeds, England, says:—I have tried the Aletris Cordial (Rio) in two cases of long standing dysmenorrhea, with excellent results. One of these patients has spent a week in bed every month for two years. After all the usual remedies, I put her on Aletris Cordial, and for the last two periods she has been out and about all the time.

L. M. WATSON, M. D., Delhi, Ills., says:—I have used Aletris Cordial (Rio) in cases of dysmenorrhea. suppressed menses and threatened miscarriage, and also, combined with Celerina, as a tonic after confinement, with the happiest results, and now I am using it on a case of leucorrhea, with injections of S. H. Kennedy's Extract of Pinus Canadensis, and it is acting like a charm.

P. H. OWEN, M. D., Morganville, Ala., says:—I have prescribed Aletris Cordial (Rio) in several cases with the most satisfactory results, and regard it as the best uterine tonic I have met with in a professional experience of over twenty-five years. In cases of threatened miscarriage it acts like a charm. Would recommend its continuous administration in all cases when there is any indication of miscarriage.

Dr. W. BERTHELOT, Santander, Spain, says:—I have tried the Aletris Cordial (Rio), and it has seemed to me to be useful, especially in cases of dysmenorrhea.

Dr. RASQUINET, Jupile, near Liege, Belgium, says:—I tried Aletris Cordial (Rio) in the case of a woman who had had several miscarriages at the end of five months, and who is now again pregnant, having reached the seventh month, thanks to Aletris Cordial.

R. REECE, M. R. C. S., Walton-on-Thames, England, says:—Aletris Cordial (Rio) in painful menstruation is most valuable. A wife of a minister suffered much, and had had three miscarriages. I prescribed Aletris Cordial. She has for the first time, gone her full time, and was safely confined with a male child.

J. T. COLLIER, M. D., Brooks, Me., says:—I have used your Aletris Cordial (Rio) in cases of females at the menopause. Consider it one of the finest remedies for these cases.

Dr. GORDILLON, St. Amand, France, says: I have tried the Aletris Cordial (Rio) in a case of dysmenorrhea. The result I obtained from the use of your preparation was excellent, better than I had obtained in the same patient by prescribing the usual remedies employed in such cases.

W. F. TOOMBS, M. D., Morrillton, Ark., says:—I have used a great deal of your Aletris Cordial (Rio) and I find it all you claim for it in amenorrhea, dysmenorrhea, metritis, leucorrhea; I don't think it has an equal. I have used it in two cases of threatened miscarriage and the trouble was obviated. For a general Uterine Tonic I know of nothing superior.

R. D. PATTERSON, L. R. C. S. &c., Medical Officer, Caledon Dispensary, Co. Tyrone, Ireland, says:—I have very great pleasure in testifying to the very high opinion I hold of Aletris Cordial (Rio) in threatened miscarriage.

NON-ALCOHOLIC. NON-RESINOUS.
BLAND AND NON-IRRITATING.

Fluid Hydrastis.

A solution of definite strength and reliability, representing all the valuable constituents of the drug—the offensive and irritating resins being rejected. The only perfect representative of the drug in the fluid form within reach of the medical profession. Though often attempted, it has never been successfully imitated.

Send for our pamphlet on "Hydrastis and its Preparations."

☞ *Physicians who have been disappointed in the use of favorite Prescriptions have the remedy in their own hands.*

Prescriptions and orders should read "Wm. S. M. Chem. Co."

GREEN DRUG
FLUID EXTRACTS.

——CHARACTERISTICS.——

Uniform Strength, Convenience of administration,
Non-liability to deterioration by age,
Positive therapeutic efficacy.

The WM. S. MERRELL CHEMICAL CO. will not hold themselves responsible for the identity of Fluid Extracts, filled out by druggists from bulk stock, even though the written label may read "*Merrell's.*"

CAUTION—accept original packages only.

☞ *Read our Monograph—Green Drug Fluid Extracts—Their origin, history, and rationale.*

Sent free to any address.

PRICE REDUCED.

True Salicylic Acid.

CRYSTALLIZED FROM
WINTERGREEN OIL.—ITS NATURAL SOURCE.

DR. P. W. LATHAM, Downing Professor of Medicine at Cambridge (England), lecturing on the treatment of gout and rheumatism at the Royal College of Physicians, says:

"The true Salicylic Acid obtained from the vegetable kingdom must alone be employed. If you have to give large doses, avoid giving the artificial product obtained from carbolic acid, however much it may have been dialyzed and purified. Give the acid without any alkali or base," etc.

A reprint of this exceedingly valuable paper will be sent on application.

A DESIDERATUM—not always appreciated.

The quality of medicines used in the prescription is as important a factor in the cure of disease as a correct diagnosis; and a physician violates no code, either of ethics or morals, in demanding of his druggist that which he knows to be reliable, instead of leaving to the latter to decide whose preparations he shall or shall not use.

TO EACH SUBSCRIBER.

---o---

Dear Doctor:

I beg your co-operation in endeavoring to get all the subscribers to the MEDICAL AND SURGICAL REPORTER to cordially accept a condition usual with first-class periodicals, that is, that subscriptions shall be paid in advance. There are still some of our subscribers who have accounts unsettled for the year 1888, and they are urged to pay this amount and the price for the year 1889 as soon as possible.

The evidences of approval of the REPORTER by medical men are multiplying. The subscription list is growing larger, and it is hoped that all who are now subscribers will long continue their patronage, and that they will heartily support the publisher in endeavoring to maintain those principles of business which experience shows to be best for all, not only for the publishers but for also the subscribers.

SO SEND WHAT YOU OWE, SOON.

Make all checks or money-orders payable to

CHARLES W. DULLES.

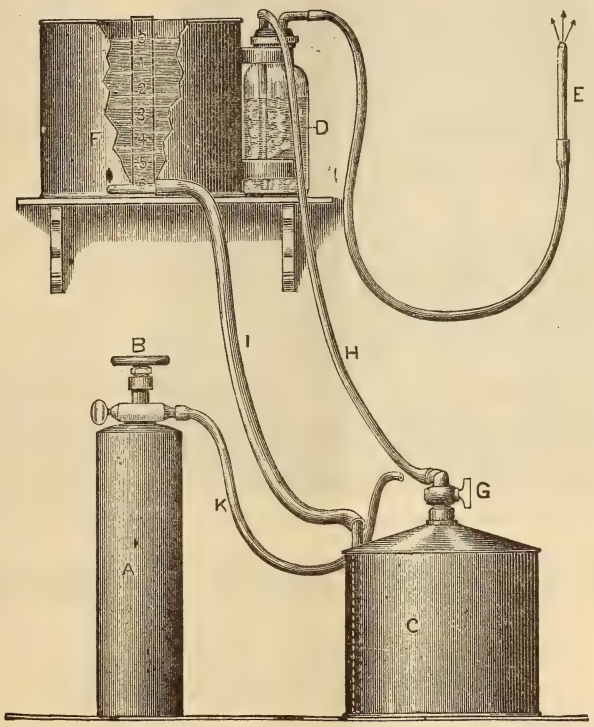
PURE OXYGEN

AND

APPARATUS FOR ITS THERAPEUTIC ADMINISTRATION



At the solicitation of a number of medical practitioners interested in oxygen treatment, we have devised apparatus for the therapeutic administration of this gas both by inhalation and by enema. We present an illustration of the latter. It is provided with a gauge by which the quantity of gas administered can be readily ascertained. We believe the apparatus we offer will be found to be the most convenient and economical device for the purpose on the market. We are prepared to supply Pure Oxygen Gas, or a mixture of Oxygen and Nitrous Oxide in definite proportions respectively of 20 per cent. and 40 per cent. of Nitrous Oxide, in cylinders of 40 or 100 gallons each. Full directions sent with each apparatus.

PRICES.

ENEMA APPARATUS	$12.00
INHALING APPARATUS	5.00
FORTY GALLON CYLINDER	6.00
FORTY GALLON CYLINDER FILLED	8.00
ONE HUNDRED GALLON CYLINDER	15.00
ONE HUNDRED GALLON CYLINDER FILLED	20.00

The Gas whether pure or mixed is supplied at the uniform price of 5 cents per gallon. The cost of the cylinders will be refunded on their return empty, with the valves in good condition.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

ST. LOUIS, MO.

An Important Communication
TO PHYSICIANS.

Thirteen years have now elapsed since the introduction of SCOTT'S EMULSION of PURE NORWEGIAN COD LIVER OIL with HYPOPHOSPHITES of LIME and SODA, since which time its growth and development have been very large, not only in this country but in South America, Great Britain and a large part of Continental Europe, and it has, in a very large degree, supplanted the Plain Cod Liver Oil. Its success is largely due to the happy combination of all its components, making a perfect chemical union, that will not separate for years, which we believe is not true of any other Cod Liver Oil preparation.

The innumerable reports from Physicians, of the brilliant results obtained justifies the statement that in almost every case where Cod Liver Oil is indicated, Scott's Emulsion is infinitely superior.

Physicians who have never tried this Emulsion, or who have been induced to try something else in its stead, will do us the favor to send for sample, and we know they will always use it in preference to plain Cod Liver Oil or any other preparation.

We also call your attention to the following preparations:

CHERRY-MALT PHOSPHITES.

A combination of the tonic principles of Prunus Virginiana, Malted Barley, Hypophosphites of Lime and Soda, and Fruit Juices. An elegant and efficient brain and nerve tonic.

BUCKTHORN CORDIAL (Rhamnus Frangula.)

Prepared from carefully selected German Buckthorn Bark, Juglans Bark, and Aromatics. The undoubted remedy for Habitual Constipation.

Be sure and send for samples of the above—delivered free.

GENUINE BLAUD'S PILLS.

These pills, which have been inserted in the new French Pharmacopœia, have been employed with the greatest success for more than fifty years by most French and foreign physicians, to cure anemia, chlorosis, and all chlorotic affections in which iron is indicated.

Here is the opinion of men most eminent in medical science who have employed them:

"For thirty-five years, in which I have practised medicine, I have recognized the incontestable advantages of BLAUD'S PILLS over all other ferruginous preparations, and I regard them as the best anti-chlorotic."—DR. DOUBLE, *Ex-President of the Academy of Medicine.*

"Of all the ferruginous preparations, which have given good results in the treatment of chlorotic affections, BLAUD'S PILLS appear to us to deserve to hold the first rank."—*Dictionnaire universel de médecine*, Vol. II, p. 99.

These pills, prepared according to the genuine formule of the originator, by his nephew, Aug. Blaud, Pharmacist of the Faculty of Paris, are sold only in bottles of 200 pills and half bottles of 100 pills, at a cost of 5 and 3 francs ($1.00, and seventy-five cents), and never in smaller quantities. *See that his name is stamped on each pill.* **PARIS, 8 RUE PAYENNE, and at every Pharmacy.** (Beware of imitations.)

BLAUD

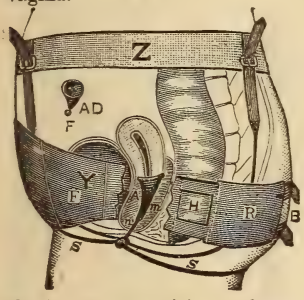
STAUFER'S

UTERINE SUPPORTER

HARD RUBBER. SPRING STEM.

This supporter, as now made, is the result of seventeen years' experience in manufacturing instruments for the treatment of displacements of the womb, aided by the suggestions of a large number of practitioners who have used these well-known supporters in the past.

The construction of the instrument shown in the cut is such that the cup inclines forward, and this inclination, together with the curve in the stem adapts it to the axis of the uterus and vagina.



There is a Coil-spring in the tube at *m*, which prevents shock to the womb when the patient sits down.

The instrument is held in position by means of a belt (Z or Y) and elastic cords (S S). One form of belt (Z) surrounds the waist; another (Y) is made like an abdominal supporter. The belts are made of 3-ply, fine cotton material, with elastic hip-straps, and buckle at the back.

Self-Sustaining Supporter.—The supporter may also be used without a belt, when no great bodily exertion calls for the latter. A little stem (F) is screwed on the cup (A), instead of the longer stem (*n*), as shown in the figure A D, and the instrument becomes self-sustaining.

The cup is made in sizes ranging from $1\frac{1}{4}$ inches to $2\frac{1}{4}$ inches in diameter, the difference from one size to another being $\frac{1}{8}$ inch. The size most frequently used is $1\frac{3}{4}$ inches across the cup.

SELECTION In ordering, give exact measure around the hips, just below crest of ilium, and the width of cup on top, as nearly as this can be estimated.

EXCHANGE Dr. Staufer will exchange one size of the supporter for another, if desired. PROVIDED the request is made within a reasonable time, and when the *three rubber parts* are returned in good condition.

THE BELTS ARE NOT EXCHANGED.

Because they are apt to show the effect of use, and there is no trouble about getting a good fit, if the correct measure is sent.

PRICE

The instrument complete, with belt Z, costs	$4.00
" " " " " Y, "	5.00

BUFFALO LITHIA WATER

IN THE TREATMENT OF

ALBUMINURIA, WHETHER OF BRIGHT'S DISEASE, PREGNANCY, OR SCARLET FEVER.

Dr. WM. B. TOWLES, Professor of Anatomy and Materia Medica in the Medical Department of the University of Virginia.

"BUFFALO LITHIA WATER, No. 2, belongs to the ALKALINE or, *perhaps, to the* ALKALINE-SALINE Class, *for it has proved far more efficacious in many diseased conditions than any of the simple* ALKALINE *waters.*

. . . . . .

"*Its effects are marked in causing a disappearance of* ALBUMEN *from the Urine.* In a single case of BRIGHT'S DISEASE OF THE KIDNEYS I witnessed *decided beneficial results from its use, and from its action in this case I should have great confidence in it as a remedy in certain stages of the disease.*"

Dr. GRAEME M. HAMMOND, of New York, Professor of Diseases of the Mind and Nervous System in the New York Post-Graduate Medical School and Hospital.

"In *all* cases of BRIGHT'S DISEASE of the KIDNEYS I have found BUFFALO LITHIA WATER *of the greatest service in increasing the quantity of urine and in eliminating the* ALBUMEN."

Dr. GEORGE W. MILTENBERGER, Professor of Obstetrics, University of Maryland,

Before the Medical and Chirurgical Faculty of the State of Maryland, recommended BUFFALO LITHIA WATER as an ALKALINE Diuretic in ALBUMINURIA of PREGNANCY.—See *Trans. Faculty of State of Maryland,* 1886.

Dr. WM. H. DOUGHTY, Professor of Materia Medica and Therapeutics, Medical College of Georgia; Member of American Medical Association, etc.

"Over the NAUSEA AND VOMITING OF PREGNANCY, PARTICULARLY IN THE LATTER MONTHS, WHERE URÆMIC CONDITIONS are possibly established, and in PUERPERAL CONVULSIONS, URÆMIA CO-EXISTING, BUFFALO LITHIA WATER often exerts *marked control.*"

Dr. CALEB WINSLOW, 23 McCulloh Street, Baltimore, Member of the Medical and Chirurgical Faculty of Maryland.

"I have found the BUFFALO LITHIA WATER, Spring No. 2, of marked service in relieving the *Nausea* of *Pregnant Women.* I frequently resort to it at intervals *during the whole course of Pregnancy.* Being *antacid, laxative, diuretic, and tonic, it seems well adapted to relieve the disturbances usually attendant upon Gestation, and I have no doubt its free use might remove* URÆMIC POISON, *and prevent Convulsions produced thereby.*"

Dr. JOS. HOLT, New Orleans, President Board of Health, State of Louisiana.

"I have prescribed BUFFALO LITHIA WATER freely in affections of the *Kidneys* and *Urinary* passages, particularly in GOUTY *subjects.* in ALBUMINURIA, and in irritable conditions of the *Bladder* and *Urethra* in *females.* The results have been such as to satisfy me *of the extraordinary value of this Water in a large class of cases usually most difficult to treat.*"

Dr. JAMES B. McCAW, Professor of the Practice of Medicine in the Virginia Medical College.

[Extract from the Proceedings of the Richmond Academy of Medicine, October 15, 1878.]

"Dr. McCaw also spoke of the great value of BUFFALO LITHIA WATER in ALBUMINURIA of *Scarlet Fever* and in ALBUMINURIA of *Pregnant Women.*"

Dr. J. T. DAVIDSON, New Orleans, La., ex-President New Orleans Surgical and Medical Association.

"I have for several years prescribed BUFFALO LITHIA WATER, Spring No. 2, in all cases of *Scarlet Fever,* directing it to be drunk *ad libitum, with the effect of relieving all traces of* ALBUMEN *in the urine,* and have found it equally efficacious in renal diseases requiring the use of alkaline water."

Dr. G. W. SEMPLE, Hampton, Va., President Medical Society of Virginia.

"In SCARLET FEVER I have known BUFFALO LITHIA WATER *restore a healthy and abundant secretion of Urine, when it was highly charged with* ALBUMEN *and the secretion almost suppressed.*"

Dr. MARTIN L. JAMES, of Richmond, Va., Professor of Materia Medica and Therapeutics, Medical Society of Virginia.

[Proceedings of the Richmond, Virginia, Academy of Medicine, December 16, 1880.]

"The President of the Academy, Dr. M. L. James, reported a case of *Congestion* of the *Kidneys* in a lady eight months advanced in *Pregnancy, attended by marked Œdema,* both over the extremities and surface, and by URÆMIC POISONING *to such an extent as very seriously impaired the vision of the patient,* relieved by the free use of this Water for three weeks.

"Other remedies, he stated, were used in these cases, *but the favorable results seemed clearly attributable to the action of the Water.*"

Dr. HARVEY L. BYRD, of Baltimore, President and Professor of Obsetrics and Diseases of Women and Children in the Baltimore Medical College, formerly Professor of Practical Medicine, etc.

"I have prescribed BUFFALO LITHIA WATER with the most satisfactory results, both as a *remedy* and *prophylactic* in the *Parturient* or *Pregnant Puerperal Eclampsia* or *Convulsions; and I may say that I know of no remedy of equal efficacy with the Water of Spring No. 2 in Sequelæ of Scarlatina.*

"It has an *ascertained value* in BRIGHT'S DISEASE. *A knowledge of its action in that disease thus far would seem* to warrant the belief that it would, in many instances, *at least in its early stages, arrest it entirely, and in its more advanced stage prove a decided comfort and palliative.*

Water in cases of one dozen half-gallon bottles, $5.00 per case at the Springs.

THOMAS F. GOODE, Proprietor,

BUFFALO LITHIA SPRINGS, VIRGINIA.

The Curd of Cow's Milk
Made as Soft and Digestible as that of
Woman's Milk.

"From experiments which I have recently made — and my thanks are due to Prof. Salisbury of the Woman's Medical College, for assistance — it seems that the claim which is made by the advocates of the MELLIN'S FOOD is true, and that the addition of this food to cow's milk does cause it to break up in very small, flaky curds."— *Dr. Chas. Warrington Earle, Professor of Diseases of Children, Woman's Medical College, Professor of Obstetrics, College Physicians and Surgeons, Chicago, in his paper on Infant Feeding, before the American Medical Association, May, 1888.*

Any physician having a case in which he desires to test MELLIN'S FOOD can obtain a sample sufficient for trial, free of all expense, by application.

Doliber-Goodale Co., Boston, Mass.

Mt. Solon, Va., January 19, 1889.

Charles W. Dulles, M.D.,

Dear Sir: The Daily Pocket Record was received yesterday. Accept my thanks for prompt sending. I thought I had remitted the price of a book for 60 patients ($1.25) a week, and find the one sent is for only 30 patients a week. Did you make a mistake?

I have used all sorts of Pocket Records, but have found your record the most desirable for a country physician's use of all the forms I have tested in the last thirty years,

Respectfully,

Jas. T. Clarke, M.D.

[See advertisement on Page VI.]

PHYSICIANS' LEDGER

Think how much time you have spent in this year over your accounts, and what another it has been to make out your bills!

Now one of the great merits of

The Model Ledger

is that it enables a physician to make out his bills with great ease. Beside this, it tells at a glance just how much he has earned in any quarter; how much he has received; and how much is still due him. These are all good things for a doctor to know.

Send Four Dollars and get one. Make check or Money Order payable to

Address Charles W. Dulles

P. O. Box 843. Philadelphia.

Specimen Pages will be sent on Application.

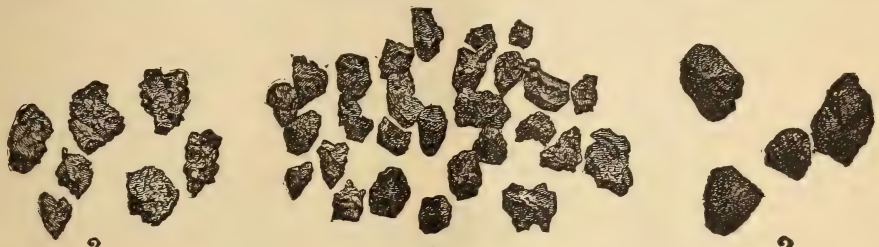
Buffalo Lithia Water

In the TREATMENT OF URINARY DEPOSIT.

Case of Dr. B. J. WEISTLING, of Middleton, Pa., stated by himself.

"Experience in its use in **STONE in the BLADDER** in my own person enables me to attest the efficacy of the **BUFFALO LITHIA WATER** in this painful malady. After having been long subjected to sufferings, the intensity of which cannot be described, I have, under the influence of this Water, passed an ounce of **CALCULI (URIC ACID)**, some of which weighed as much as four grains, affording inexpressible relief and leaving me in a condition of comparative ease and comfort.

"On one occasion I passed thirty-five **CALCULI** in forty-eight hours. The appearance of these **CALCULOUS NUCLEI** indicates unmistakably, I think, that they were all *component particles of one large* **CALCULUS** *destroyed by the action of the Water, by means of solution and disintegration.* At my advanced period of life (I am seventy-seven years and six months of age), and in my feeble general health, a surgical operation was not to be thought of, and the Water seems to have accomplished all that such an operation, if successful, could have done."



[The above plate is from a photograph, and represents the exact size and shape of some of the Calculi passed by Dr. Weistling. They were preserved by his son, Dr. J. Weir Weistling.]

Case stated by Dr. G. HALSTED BOYLAND, late Professor of Surgery, Baltimore Medical College, Member American Medical Association.

"The case of Mr. C., which came under my observation as Resident Physician at the Springs during the season of 1884, affords undoubted evidence that Buffalo Lithia Water is a **SOLVENT** *for Urinary Deposit*, commonly known as **STONE in the BLADDER.** He was operated upon for **STONE**, the operation affording but partial and temporary relief. A year afterward he visited the **BUFFALO LITHIA SPRINGS**, at the same time passing small quantities of a *Urinary Deposit*, of the **TRIPLE PHOSPHATE of AMMONIA** and **MAGNESIA VARIETY**, and his sufferings such as required that he should be kept constantly under the influence of opiates. In some eight weeks the solvent properties of the Water *were evident in the diminished consistency of the deposit, the increased quantity discharged, and by its change from Concrete Lumps to fine Sand*, which he discharged to the amount of *Four Ounces.* After a time, however, the quantity gradually diminished, and finally ceased, and he left the Springs *with the deposit dissolved* and *washed out of the system*, and the *Diathesis fons et origi morbi* altered. There had been a disappearance of the attending distressing symptoms, and great improvement in his general condition."

Dr. MARTIN L. JAMES, of Richmond, Va., Professor of Materia Medica and Therapeutics, Medical Society of Virginia.

[Proceedings of the Richmond, Virginia, Academy of Medicine, December 16, 1880.]

"The President of the Academy, Dr. M. L. James, reported three cases of marked **URIC ACID DIATHESIS** successfully treated by the Water of Spring No. 2 of the **BUFFALO LITHIA SPRINGS** of Virginia. In one of these patients there were, as a result of this Diathesis, **SANDY DEPOSITS** in the *Urine, Inflammation of the Kidneys, Irritability of the Bladder, and Hæmaturia*, and, finally, the passage of a **CALCULUS** of the size of a cherry, formed on a blood-clot as a nucleus. In another case there were frequent attacks of **NEPHRITIC COLIC**, attended by **SANDY DEPOSITIONS** in the urine. After the free use of this Water in these cases, no further manifestations of the disorder occurred."

Dr. HENRY M. WILSON, of Baltimore, ex-President Medical and Chirurgical Faculty of Maryland.

"My experience in the use of the **BUFFALO LITHIA WATER** has not been large, *but it is of such a positive character that I do not hesitate to express my preference for it, as a* **DIURETIC** in **URINARY CALCULI,** *over all other waters that I have ever used.*"

Water in cases of one dozen half-gallon bottles, $5 per case, at the Springs.

BUFFALO LITHIA SPRINGS, VIRGINIA.

THE NEW HYPNOTIC
SULFONAL-BAYER.

SULFONAL was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

SULFONAL (Diæthylsulfondimethylmethan) is in the form of colorless prisms, odorless, and tasteless, melting at 125.5° C. (258° F.) and has the composition $(C H_3)_2{=}C{=}(C_2 H_5 SO_2)_2$. It is slightly soluble in cold water, but easily soluble in hot water or alcohol.

SULFONAL was first examined as to its physiological and pathological effects by Prof. A. Kast, of Freiburg University and its hypnotic action was discovered and studied by him.

Since then SULFONAL has been the subject of numerous trials and experiments by many eminent and experienced physicians. Their testimony is unanimously favorable, and the conclusions reached by them are as follows:

SULFONAL is a prompt and reliable hypnotic, which in proper doses, produces quiet, natural sleep, lasting a number of hours.

SULFONAL has no unfavorable effects on the heart and the circulation, nor on the temperature, the pulse, or the respiration.

SULFONAL produces no disagreeable secondary symptoms; the patients with very few exceptions awake from their sleep feeling strong and greatly refreshed.

SULFONAL does not interfere with the process of digestion.

SULFONAL is a hypnotic, and not a narcotic; it acts by giving rest to the cells of the cerebral cortex, thereby causing sleep.
